New Zealand mud snail (*Potamopyrgus antipodarum*) is an invasive species which originates from New Zealand. It has spread from New Zealand to Australia, Europe, North America and Asia. The unique feature of these spread populations is that there are no males present. The mud snail can reproduce through parthenogenesis. The offspring is grown inside of the female and hatched when the offspring is ready to survive in the environment. The mud snail can be used in chronic ecotoxicological testing to test how chemicals affect the reproduction. Here, the mud snails are exposed to chemicals from the European Parliaments priority substance list and their effects to the reproduction of mud snails are followed. Polybrominated diphenyl ethers (PBDEs) are used as flame retardants. BDE-47 is one of the most common of the PBDEs in the environment and because of that it is chosen to this study. Fully brominated BDE-209 was thought not to be harmful to the biota but is now detected for example in the fish of the coast of Finland. The neurotoxic pesticide Cypermethrin is on the priority substance list because it is very toxic to aquatic organisms. It is still allowed to use as a pesticide in Finland. In the experiment the mud snails are exposed to water which has low concentrations of these chemicals. After the exposure of 28 days the embryos inside the snails are counted. The tests will show whether the chemicals affect the reproduction of mud snails by increasing or decreasing and what concentrations can cause an effect. The low concentrations of chemicals and longer exposure times are relevant to use in the study because the organisms seldom are exposed to high concentrations of chemicals and the organisms usually cannot escape the environment. Obtained results will be compared with the priority substance list's environmental quality standards and the effectiveness of the quality standard can be evaluated.

#### WE065

##### **Evaluation of the toxic effect of 3 metals and mixtures in veliger and pediveliger larvae of the Japanese oyster *Crassostrea gigas***

A.S. Sobrino-Figueroa, Universidad Autonoma Metropolitana Iztapalapa / Hidrobiologia Laboratorio Alejandro Villalobos; C. Cáceres-Martínez, Universidad Autónoma de Baja California Sur

The Japanese oyster is an introduced species that grows in coastal systems of the Mexican Pacific, due to this resource has presented problems of survival, in the present study an evaluation of effect of some of the most abundant metals in the coasts of Mexican Pacific that are: Cd, Cr and Pb and their mixtures, was performed, to know its toxicity in veliger and pediveliger larvae and its effects on larval attachment is critical stage in the life cycle of this organism. Microbioassay were performed with duration of 72 hours, where the effect of metals separately and in combinations (Cd + Cr, Cd + Pb, Cr + Pb and Cd + Cr + Pb in the ratio 1: 1) were tested, 5 metal concentrations (2.5, 1.23, 0.31, 0.078 0.019 ppm) in quintupled were used. In the tests the number of surviving organisms and the number of larvae that were fixed to a substrate was determined. The toxicity of metals was (CL<sub>50</sub> the most toxic to least toxic): Cr > Cd + Cr > Cr + Pb > Cd + Pb > Cd + Cr + Pb > Cd > Pb. The interaction of metal mixtures was potentiation in all cases, with magnification factors ranging from 1 to 3. The percentage of settlement of larvae exposed to metals and mixtures was between 2 to 18 times lower than the controls. Metal concentrations with deleterious effects are very close to those reported in sediments from some sites within the Bay of La Paz B.C.S., San Luciano B.C., and Altata Bay Sin. therefore it is required bioavailability assessments of metals on these sites.

#### WE066

##### **Development of the marine amphipod *Parhyale hawaiiensis* as a model organism for ecotoxicology**

M.C. Artal, University of Sao Paulo - USP / Toxicology and Toxicology analysis; A. dos Santos; M. Eldridge, University of New Haven; T.B. Henry, Heriot-Watt University / School of Life Sciences; G.d. Umbuzeiro, FACULTY OF TECHNOLOGY - UNICAMP / LEAL

Development of model species for conducting ecotoxicity tests that are relevant to tropical marine and estuarine ecosystems is urgently needed. The marine amphipod *Parhyale hawaiiensis* is already a model organism for developmental biology and other studies; and the worldwide distribution and importance of this species in tropical waters such as the coast of Brazil indicate that it could be an excellent model for ecotoxicity tests. Our objective is to introduce *P. hawaiiensis* as a model organism for ecotoxicology, develop standard operating procedures for husbandry and ecotoxicity testing, provide some toxicology information for this species upon exposure to reference toxicants and develop procedures for gene expression analysis. *P. hawaiiensis* were collected at Poço beach Itanhaém state of São Paulo, Brazil in 2010. Cultures were maintained in an incubator with controlled conditions that included continuous aeration, temperature  $24^{\circ}\text{C} \pm 2$ , photoperiod of 12 h and salinity of  $30 \pm 2$ . To obtain neonates of known ages for toxicity tests, adult organisms are separated from the culture and placed in smaller containers and neonates collected each day to ensure that neonates are of the same age. Toxicant ( $\text{Zn}^{2+}$  and  $\text{Cu}^{2+}$ ) exposures were conducted for 96 h, in static conditions, without feed, and one organism was exposed in 25 mL of solution with 10 replicates for each concentration. Mortality was recorded and the effect concentration 50% (EC50) was estimated by Trimmed Spearman-Kärber method. At sub-lethal toxicant concentrations, neonates were collected, preserved at  $-20^{\circ}\text{C}$ , and used for development of standard operating procedures (SOPs) for total RNA extraction, reverse transcription, and Q-PCR for assessment of metallothionein gene expression. Age-related assessment of toxicity indicated EC50 values from 0.17 to 0.62 mg/L for zinc and 0.95 to  $>19$  mg/L for copper, and age 0 neonates were selected and used for subsequent standardized tests. The EC50 for age 0 neonates was 0.30 - 0.44 mg/L for zinc and 1.09 - 3.05 mg/L for copper. On-going work will establish the SOPs for use of *P. hawaiiensis* in ecotoxicity tests and provide a new model organism for investigating the effects of toxicants in important tropical ecosystems. **Acknowledgement:** The authors thanks FAPESP (project 2014/08829-7) and CNPq (400362/2014-7) for funding and CAPES for MCA fellowship, Profs. Augusto Luchessi, Silvia Berlanga and Sylvia Stuchi.

#### WE067

##### **The effects of selective serotonin reuptake inhibitors (SSRIs), serotonin and dopamine on chromatophore expression in the crustacean *Crangon crangon***

E.M. Feuerhelm; R. Fritter, University of Portsmouth; A.T. Ford, University of Portsmouth / Biological Sciences

Neuroactive pharmaceuticals such as antidepressants found in the environment are believed to impact neurotransmitters that are present in some aquatic organisms. These neurohormones are responsible for a wide range of biological processes including behaviour, growth and reproduction. Monoamine neurotransmitters such as serotonin and dopamine are also known to affect colour physiology in crustaceans. Therefore, this study aimed to develop and optimise biomarkers for effects of selective serotonin reuptake inhibitor (SSRIs) as well investigate the role of serotonin and dopamine on chromatophore expression in the common sand shrimp *Crangon crangon*. *Crangon crangon* is an ecological and economically important crustacean found living in estuarine and sandy shore environments within the north eastern Atlantic. Shrimp ( $n \sim 12/\text{treatment}$ ) were exposed over 1 week to at three nominal Fluoxetine (Flx) concentrations (10ng/L, 100ng/L and 1000ng/L) and the black, red and yellow chromatophore expression was recorded after 1 hour, 1 day and 1 week on black and white substrates, thus testing their ability to match their background. After the week long exposure the shrimp from each concentration

were used in a choice chamber experiment where they were presented with both black and white substrates in a tank and their settlement choices were observed over 20 minutes. Results revealed specimens became significantly darker on the darker background and lighter on the light backgrounds as one might expect with their ability to avoid predation. Significant differences from the control group were noted in the chromatophore scores between concentration, background colour and time. Discriminant analysis of chromatophore grades was able to cluster into groups based on colour of the substrate and highlighted that specimens on black substrates under the highest concentrations (1000ng/L Flx) had a chromatophore distribution matching those on white backgrounds. In addition, those on light backgrounds exposed to 10ng/L Flx were darker. All specimens preferred darker backgrounds and no significant difference in choice was observed after 20 minutes. The repeatability and further development of these tests are discussed.

#### WE068

##### **Do ground beetles differ in their response to chlorpyrifos?**

F.M. Bakker, Mitox Consultants; S.B. Dehelean, Mitox Trial Management BV  
Ground beetles (Coleoptera: Carabidae) species are abundant in agricultural habitats and their surroundings. Being soil-inhabitants, soil dwellers and plant roamers, exposure to plant protection products occurs and impacts carabid abundance. Field observations indicate that species may be affected differentially. To investigate how differences in sensitivity at the level of the individual relate to the observed differences at the population level we assessed the response to varying doses of an organophosphate insecticide for different species of ground beetles and two formulations of chlorpyrifos (CS=micro-encapsulated and EC=emulsifiable concentrate). Nine ground beetle species were collected from meadows situated in an agricultural landscape in SW France. The species were kept in captivity at the test facility until used for a test. Two species, *Carabus auratus* and *Poecilus cupreus*, produced sufficient progeny to enable testing of the larvae. Individuals were weighed and the test item was administered using topical application (1 µL droplets). After dosing beetles were kept individually and mortality was assessed 72h later. With these data the LD<sub>50</sub> and NOED for the test species were calculated. Although the spectrum of species tested showed little overlap between the formulations, it is clear that the CS formulation was less toxic. For both products toxicity endpoints (LD<sub>50</sub> and LOED) were positively correlated with body weight and given the large differences in body weight these varied importantly. However, when expressed as dose per unit bodyweight there was no correlation with weight and values were of the same order of magnitude. Only *Poecilus cupreus* larvae fell outside the range (less sensitive). The results indicate that any carabid beetle can be used as an indicator for the sensitivity of other species and that species sensitivity distributions can be estimated from species weight distributions. The important next question is how species differ in exposure and how this relates to behavioural traits.

#### WE069

##### **Sensitivity of seven ground beetles species (Coleoptera: Carabidae) exposed to the organophosphate: chlorpyrifos.**

S.B. Dehelean, Mitox Trial Management BV; F.M. Bakker, Mitox Consultants  
Ground beetles communities from agricultural ecosystems have encounter changes in their structure due to pesticide exposure. The effects were not similar to all species as some abundant species reduced their numbers and other almost disappeared from these landscapes. Therefore it is important to know the individual response of species to the pesticide exposure in order to understand the changes in their communities. The aim of this study was to test the sensitivity of several ground beetles species to the organophosphate chlorpyrifos. To do so we have conducted dose-response laboratory tests, using a topical application method, on seven species: *Carabus auratus*, *Carabus violaceus*, *Carabus nemoralis*, *Pterostichus madidus*, *Harpalus rufipes*, *Badister bullatus* and *Poecilus cupreus*, captured from a natural meadow in SW France. All beetles were topically applied with 1 µL droplet of solutions with different concentrations of chlorpyrifos. Their mortality rate was assessed after 72 hours. A dose response curve was produced using a probit analysis and a LC50 (ng a.i./µL) value calculated. Our results show that the most common species, *Poecilus cupreus* and *Pterostichus madidus*, have similar sensitivity to Chlorpyrifos (LC50 values in the same order of magnitude), although they are not the most sensitive ones. Smaller species like *Badister bullatus* are more sensitive (LC50= 40.09 ng a.i./µL) than larger species as *Carabus violaceus* (LC50= 5565 ng a.i./µL). These results are in contradiction with field observation, in which chlorpyrifos had a higher effect on the abundance and recovery rate of species from the genus *Carabus*. The difference between the results of the laboratory tests and field observation suggest an influence of different factors on the toxicity of chlorpyrifos to the ground beetles. The next questions to be answered are: what is the nature of these factors and how do they influence the toxicity response.

#### WE070

##### **Assessment of the quality of riparian soils by the earthworm *Eisenia andrei*: contribution to toxicity of the different chemicals**

S. Sforzini, Università Del Piemonte Orientale Amadeo Avogadro / Department of Sciences and Technological Innovation DiSIT; M. Boeri, University of Piemonte Orientale; A. Oldani, Renewable Energy & Environmental R&D Center - Istituto eni Donegani; F. Vago, eni S.p.A-Direzione Ricerca ed Innovazione Tecnologica,

Centro Ricerche per le Energie non Convenzionali; r. borrelli, Corporate; P. Cesti, ENI S.p.A. / Direzione Ricerca ed Innovazione Tecnologica, Centro Ricerche per le Energie non Convenzionali; L. Zaninetta, Syndial / Environmental Remediation; A.G. Viarengo, Università del Piemonte Orientale / Department of Sciences and Technological Innovation DiSIT

Riparian areas play an important role in river ecosystems. In flood condition, the river water penetrate into these zones, carrying fine materials but also contaminants potentially present in the water body. In this study, a battery of biomarkers was utilised in the earthworm *Eisenia andrei* to assess the quality of riparian soils contaminated with organic and inorganic pollutants (such as PAHs, PCBs, DDT, Hg, Cu, Zn, etc.). In addition to high-level endpoints such as survival and reproduction, the responses of more sensitive sublethal parameters were investigated i.e. i) biomarkers of stress identifying effects at different levels of functional complexity evaluated in different cells and tissues of worms and ii) biomarkers of exposure to specific classes of contaminants (such as heavy metals and pesticides). When earthworms were incubated for 28 d in the contaminated soils, no effect was found in the survival of the organisms and the number of juveniles showed no alteration with respect to controls. Only a minimal non significant change was observed in lysosomal membrane stability of coelomocytes. However, in these cells, an alteration of mitochondrial functionality and the generation of reactive oxygen species was found, but this low-level oxidative stress caused no damage to the cell plasmamembranes as highlighted by the results of the lactate dehydrogenase release in the coelomic fluid. In the cells of the chloragogenous tissue we found an alteration of lipid metabolism manifesting as lysosomal accumulation of neutral lipids. Moreover, in this tissue, the lysosome/cytoplasm ratio presented a significant increase with respect to controls, indicating increased autophagy. Biomarkers of exposure did not show significant changes. Taking into account the concern of the human population to particular classes of contaminants such as DDT and its metabolites DDD and DDE, we experimentally verified the role of these pollutants in causing the stress syndrome in the organisms. In earthworms exposed to 12.52 ppb DDX (concentration found in the contaminated soils - a value slightly higher than the Italian law limits) no toxic or genotoxic effect was observed. These results highlight the importance of the use of ecotoxicological tests to assess the contribution of a particular class of pollutants in the toxicity of a matrix. However, the possible additive, synergistic or antagonistic effects of the chemicals present in the soils should be always considered.

#### WE071

##### **Assessment of the population dynamics of *Folsomia candida* (Collembola) and its life history characteristics in relation to temperature**

V. Roeben, RWTH Aachen University, Institute for Environmental Research / Institute for Environmental Research BioV; S. Treidy, RWTH Aachen University / Institute for Environmental Research BioV; M. Ross-Nickoll, RWTH Aachen / Institute for Environmental Research BioV; A. Schaeffer, RWTH Aachen University / Institute for Environmental Research; T.G. Preuss, Bayer CropScience / Environmental Modelling

In a previous study we developed the individual-based model FOLCAS which simulates the vertical dispersal and possible pesticide exposition of *Folsomia candida* (Collembola) in an agricultural soil column. Through this work it became obvious that detailed data on specific life history parameters of collembolans is still scarce. This work presents two experimental sections: an investigation of the population dynamics of *F. candida* and the scrutiny of life history characteristics in relation to temperature. In order to assess the population dynamics of *F. candida* 10 individuals aged 9-12 days were placed on activated charcoal plates and kept at 20°C. The population was monitored for 11 months. Photos were taken at least on a weekly basis for counting. The results showed that the population size rapidly increased until it reached a density of about 22 ind./cm<sup>2</sup> after 10 weeks. Subsequently, the population size slowly decreased. In this phase no vital egg deposition was observed. After nine months population density reached a low and shortly after, *F. candida* started vital egg deposition again. Another approach using different food levels indicated that excessive food availability does not necessarily lead to higher population densities but rather decreases those in comparison to intermediate and low food concentrations. In a second experiment life history parameters of *F. candida* in relation to temperature were investigated. In order to assess the life expectancy of *F. candida* 15 eggs were transferred onto activated charcoal plates. The eggs were stored at 4°C, 15°C, 20°C, 24°C and 30°C. Subsequently, the hatching success and the longevity of the original generation were observed. This generation was transferred to fresh plates as soon as their offspring approached their size in order to distinguish the different generations. Eggs stored at 4°C and 30°C did not hatch. Less hatching success was observed at 24°C accompanied by reduced life expectancy in comparison to cooler temperatures (15-20°C). In addition, results of cooling experiments investigating overwinter survival will be presented. The results of the study will present new data for the otherwise well investigated Collembola species *F. candida*. In the next step the results will be used to refine species related procedures in the vertical distribution model FOLCAS, such as density-dependent mortality and reproduction and the life expectancy.

#### WE072

##### **Using a transcriptomics approach to unravel mechanisms of action of**

#### pesticides in *Folsomia candida*

T.F. Simoes, Polytechnic Institute of Leiria / ESTM GIRM; S.C. Novais, Polytechnic Institute of Leiria / ESTM and GIRM; T. Natal-da-Luz; J. Renaud, Department of Life Sciences; J. Sousa, University of Coimbra / Department of Life SciencesCEF; T. De Boer, Vrije Universiteit / Ecological Sciences; D. Roelofs, Vrije Universiteit / Inst of Ecological Science; N.M. van Straalen, VU University Amsterdam / Department of Ecological Science; M.F. Lemos, Instituto Politécnico de Leiria / Dept Biology

Ecotoxicogenomics is a powerful tool to spot early molecular events involved in toxicant responses which are responsible for the adverse effects observed at higher levels of biological organization. Clear advantages come from linking the information of the phenotypic consequences of stress with the molecular determinants (genes) that are induced or suppressed after it. Taken together, phenotypic and transcriptomic data will help not only to unravel the mode of action of the stressor but also which components might be affecting the survival, growth, and reproduction of a given species, which may impact the population and ultimately the community. It is accepted that toxicity can be detected at the sub-cellular level earlier than it is observed at higher levels of biological organization. *Folsomia candida* is a common and widespread arthropod that occurs in soils throughout the world and has been used as a “standard” test organism for more than 40 years for estimating the effects of pesticides and environmental pollutants on non-target soil arthropods. This species is very sensitive to organic compounds and is among the most sensitive representatives of its taxon. In the present study, *F. candida* was used as test organism and its survival and reproduction was assessed (ISO 11267:1999(E)) after exposure to the herbicide glyphosate (30.8 % Montana®) and the fungicide chlorothalonil (38.8% Bravo®500) in a Portuguese agricultural soil. Organisms were then exposed for 10 days to the reproduction EC<sub>50</sub> of each pesticide (glyphosate: 4.95 mg a.i./kg; chlorothalonil: 127.31 mg a.i./kg) as well as to control conditions, with sample collection at days 2, 4, 7 and 10. RNA was extracted from each pool of organisms and RNA sequencing yielded different sets of differentially expressed genes after exposure to each pesticide. Gene Ontology enrichment analysis identified distinct biological processes and molecular functions to be affected. Moreover, the pattern of gene expression changed over time. This work constitutes the first attempt to understand the mechanisms of toxicity behind the effects of glyphosate and chlorothalonil in soil invertebrates which can be used to develop a more effective set of tools to assess the early effects of such pesticides in a real scenario of soil contamination.

#### WE073

##### Toxicity Effect of Strain *Bacillus thuringiensis. berliner* on Domestic Silkworm (*Bombyx mori*)

Y. Bu, Nanjing Institute of Environmental Sciences; F. Shen, C. Liu, Nanjing University; C. Dai, Nanjing Normal University; Z. Shan, Nanjing Institute of Environmental Sciences MEP

As an extensively applied and the most successful pathogen used for insect control, *Bacillus thuringiensis* (Bt) presently occupies ~2% of the total insecticidal market (Bravo *et al.*, 2011). Nearly 200 kinds of Bt products derived from different Bt strains have been registered in the U.S. by 1998 (Schnepf *et al.*, 1998). *Bombyx mori* which belongs to Lepidoptera Bombycidae is a commercially important insect for production of silk and recombinant proteins, and is also a good model lepidopteran (Goldsmith *et al.*, 2005; Nagaraju and Goldsmith, 2002). It's sensitive to Bt pesticides because of the similar classification with Bt targeted insects and may be poisoned by mulberry leaves contaminated by Bt pesticides used in mulberry field and surrounding farmland directly or indirectly through water, air and other means (Zhu *et al.*, 2008). This study aimed to evaluate the toxicity of strain *Bacillus thuringiensis. berliner* (Bt.22945 for short) on silkworm *Bombyx mori* in four aspects including acute toxicity, proliferation toxicity, chronic toxicity and infectious toxicity. Using food intake method, high concentration of fermentation up to 10<sup>9</sup> spores/ml caused strong acute toxicity to 2nd and 4th instar larvae, and LC<sub>50</sub> (2d) were 1.44×10<sup>8</sup> spores/ml and 5.55×10<sup>8</sup> spores/ml, respectively. After feeding 5th instar with fermentation of 1.89×10<sup>8</sup> spores/ml, fluorescence quantitative PCR showed that *cryI* gene of Bt didn't show proliferation, and the copy number reduced to 342.4 copies/ml after 2 d. Chronic Bt exposure to 2nd instar larvae showed that 10×group's weight was remarkably lower than control group, but 50× and 100× groups had no significant difference as compared to control group before cocooning and middle of 3rd instar. The morphology and biochemical reaction of strain isolated from the dead larva infected with Bt.22945 were identical with original Bt.22945, and DNA sequencing showed that 16S rRNA gene of the strains had 99% similarity. The reinfected causing death test further confirmed that Bt.22945 was the infective pathogen of silkworm. The results showed that Bt.22945 was pathogen of silkworm with strong acute toxicity, and the usage of Bt products near mulberry fields should needs more environmental risk concerns. **Key words:** *Bacillus thuringiensis*; silkworm; toxicity assessment; proliferation; \n \n

#### WE074

##### The toxicity of neonicotinoids to mayfly nymphs and their seasonality.

P.J. van den Brink, Alterra and Wageningen University; R.S. Bekele, J.M. Van Smeden, Wageningen University; I. Roessink, Alterra  
In this study the neonicotinoids imidacloprid, thiacloprid and thiamethoxam were

evaluated for their acute and chronic toxicity to mayfly nymphs (*Cloeon dipterum*) under laboratory conditions. Acute toxicity experiments performed at different temperatures showed that *C. dipterum* was less sensitive to imidacloprid at lower temperature. The LC50,96h were a factor of 4.2 higher at a temperature of 10 °C compared to 18 °C. The differences were less pronounced for the EC50,96h (factor of 1.7). Interestingly the autumn generation of *C. dipterum* proved to be less sensitive to imidacloprid than the earlier tested summer generation (factor of 5.7 of difference between the EC50,28d; Roessink *et al.*, 2013). The acute toxicity data showed that all three chemicals were equally toxic when based on LC50,96h (34 – 52 µg/L) while thiacloprid was a factor of two more toxic when based on EC50,96h (10 – 25 µg/L). The chronic toxicity data also showed that thiacloprid was twice as toxic to *C. dipterum* compared to the other two compounds (EC50,28d between 0.29 and 0.68 µg/L).

#### WE075

##### Delayed metamorphosis in Africanized *Apis mellifera* exposed to the imidacloprid.

H.M. Soares, Departamento De Biologia; D.A. Tavares, Universidade Estadual Paulista Julio de Mesquita Filho / Departamento de Biologia Centro de Estudo de Insetos Sociais Rio Claro São Paulo; E.C. Silva Zacarin, Universidade Federal de São Carlos / Departamento de Biologia Laboratório de Biologia Estrutural e Funcional Sorocaba São Paulo; R.C. Nocelli, Ciências Biológicas / Departamento de Ciências da Natureza Matemática e Educação; O. Malaspina, Universidade Estadual Paulista UNESP

The indiscriminate application of pesticides is reducing the population of pollinators, such as bees, in agroecosystems. Honeybees that plays role inside the hives, as well as the larvae, can be exposed to environmental contaminants brought by foragers. Adult bees and larvae can ingest nectar and pollen contaminated with insecticides, particularly those with systemic characteristic, such as imidacloprid. This study investigated the effects of insecticide on larval development of the honeybee Africanized *A. mellifera*. During the first 5 days of development, the larvae are in the feeding period and are found at the bottom of brood cell. At the end of the feeding phase, the larvae begin to get a vertical position, the gut empties its contents and then they begin the prepupal stage. Thus, larval position inside the artificial cupule and defecation are important events prior to metamorphosis. Preliminary results of these parameters in larvae orally exposed to different concentrations of imidacloprid showed that the individuals delayed the verticalization inside the cupule and the defecation, from the 250 and 500 ng a.i./µL of diet, respectively. Further investigations are necessary to understand how these developmental delays could impair behavior and survival of the bees after the emergence.

#### WE076

##### Reaslistic toxicity of neonicotinoid insecticides in the aquatic environment

V. Carrasco Navarro, University of Eastern Finland / Biology  
Neonicotinoid insecticides are the most widely used insecticides worldwide and have been on the spot recently due to the apparent toxic effects caused to bees. As a consequence, their use was restricted to a great extent in the EU for two years. The neonicotinoid insecticides that have been on the spot are clothianidin, imidacloprid and thiamethoxam. Although neonicotinoids are intended to treat crops from pests, a high proportion of the insecticide may easily leach to the surface waters after application as their solubility is high. They have been detected in environmental waters from all around the World. Although they allow a faster and healthier growth of crops by aiming at pests, neonicotinoids can be toxic also to non-target organisms, for example, the presence of imidacloprid had a negative effect on the population of aquatic invertebrates. Although we know that neonicotinoids may be toxic to non-target organisms their joint toxicity in mixtures of chemicals is the subject of very few studies. Toxicity testing of many chemicals at a time would be highly relevant, since that is how chemicals are likely to exist in the environment. The toxic effects of co exposure of neonicotinoids as part of the complex mixture pollutants existing in the surface waters is currently completely unknown subject. This is the subject that this research proposal is going to tackle. Using the model organisms *Lumbriculus variegatus* and *Chironomus riparius*, the toxicity of neonicotinoids and other relevant contaminants is going to be tested in aquatic laboratory exposures. Sublethal endpoints such as survival rate, biomass and reproduction will be measured over 28 days and compared among different treatments of animals exposed to single neonicotinoids and in the presence of other chemicals. Over the 28 days treatments, the toxicity will be assessed every week by setting 4 timepoints. The hypothesis is that the addition of other chemicals (modifying the single-chemical testing conditions) may cause a synergetic effect, increasing the toxicity of neonicotinoids, although also scenarios of antagonistic or no change in toxicity may occur. Experiments that study the toxicity caused by more than one substance are very relevant and can help to unveil what occurs in the real world. The results obtained will be meaningful in addressing the environmentally relevant situation when it comes to effects of pollutants and will be relevant for Finnish and European environmental authorities.

#### WE077

##### Integrated toxicogenomics and comparative behavior analysis on toluene and formaldehyde exposed fruit fly *Drosophila melanogaster*

H. Eom; Y. Chung, University of Seoul; K. Song, Korea Environment and

Merchandise Testing Institute; T. Chon, Pusan National University; J. Choi, School of Environmental Engineering Graduate School of Energy and Environmental system Engineering

Behavioral monitoring fills the gap between macro-scale (e.g., community structure) and micro-scale (e.g., molecular response) measurements effectively in risk assessment. Since behaviors reflect integrated processes on the subcellular, cellular, physiological, and individual level responses, behavioral measurements are considered as comprehensible endpoints in detecting disruption from a broad spectrum of chemicals and environmental stresses. Though *Drosophila melanogaster* behavior-related research has been conducted in various aspects, a few studies are available on the relationship between chemical-induced gene level alteration and behavior responses in toxicological context. In this study, toxicity of toluene and formaldehyde was investigated on the model organism, *Drosophila melanogaster* using comprehensive toxicogenomics and comparative behavior analysis. Microarray result indicated the numbers of genes differentially expressed by toluene and formaldehyde were 37 and 130, respectively. Ingenuity pathway analysis revealed that NF-Kb as an herb molecule in formaldehyde mediated toxicity, while MTTP and beta estradiol were found to be highly linked by toluene exposure. To explore physiological meaning of toluene and formaldehyde -induced genes and pathways, we selected loss-of-function mutants of genes and pathways popped up in microarray followed by pathway analysis, which are *Dsor1*, *p38b*, *bsk*, *puc*, *msn*, *Hsp23*, *p53*, *yl*, and *Thoc7*. Toluene and formaldehyde were exposed to *wildtype* and selected mutants through inhalation chamber for 72 h and survival and alteration of locomotive movement were analyzed. Intensive computational behavior analysis was further conducted on *wildtype*, *p38b* and *p53* mutant *D. melanogaster*. Movement of *D. melanogaster* was continuously observed by using computer interfacing techniques and was analyzed by permutation entropy (PE) after exposure to toluene and formaldehyde. Overall results provide valuable information on indoor air pollutant biomonitoring using an alternative animal model. This study also indicate that behavior changes might reflect altered gene expression, which lead to consider behavior parameter as higher level toxicity indicator of chemical-induced gene expression. Gene and behavior interaction by chemical exposure in *D. melanogaster* can provide an insight of the relationship between toxic mechanism of action and higher level effect.

## Multistress in aquatic environments: the big picture (P)

### WE079

**Evaluation of the genetic and physiological effects of Decabromodiphenyl ether (BDE-209) and Dechlorane plus (DP) in *Mytilus galloprovincialis* by a novel *in vivo* exposure via the dietary pathway.**

E. Barón; A. Dissanayake, University of Plymouth / School of Biological Sciences; J. Vila, IDAEA CSIC Barcelona; J. Readman, School of Biological Sciences; A.N. Jha, Plymouth University / Biological Sciences; E. Eljarrat, IDAEA-CSIC / Department of Environmental Chemistry; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research

Polybrominated diphenyl ethers (PBDEs) have been used as flame retardants (FR) for many years and their concentration levels have been reported in different environmental and biotic matrices. Commercially, they were available in three different mixtures: Penta-BDE, Octa-BDE and Deca-BDE. Penta- and Octa-BDE mixtures were banned in 2008 in the European Union and production of Deca-BDE was meant to end by the end of 2013. Thus, commercial demand of alternative halogenated flame retardants increased with the purpose of replacing PBDEs in polymer formulations. Dechlorane plus (DP) is an halogenated norbornene which was proposed by the EU as a replacement of Deca-BDE. Both classical and alternative flame retardants BDE-209 and DP have shown bioaccumulation and biomagnification potential. In general, there is a gap in the knowledge of the toxicological effects that these compounds may have. In addition, while some studies evaluated the effects of PBDEs in mussels (mainly focused on BDE-47) to the best of our knowledge this is the first *in vivo* exposure to DP in bivalves. Mussels were exposed to BDE-209 and DP at three concentrations for six days. BaP was used as *in vivo* positive control while acetone was used as negative control (n=9 per treatment). Exposures were conducted via dietary pathway, validated previously with BaP. Hydrogen peroxide was used as an *in vitro* positive control. Following exposures, clearance rate (CR) was measured and the alkaline COMET assay was performed immediately thereafter. CR were significantly higher than the control in all cases ( $p < 0.001$ ), but no statistically significant differences were observed among the different treatments at any of the three time points evaluated. The *in vivo* exposures to BDE-209 and DP showed significant genetical damage at different concentrations in both cases. Furthermore, differences between the two compounds were observed at the different concentration levels of exposure. DP showed, at lower levels of concentration, similar DNA damage than BDE-209, which could suggest that it has a higher genotoxic potential. Moreover, our results showed that CR of the mussels was not affected at these doses. Therefore, results indicate that mussels are more likely to be affected by these contaminants at the genetic level but not at the physiological level. Since DP has been proposed as an alternative to BDE-209, further investigation regarding its toxicological properties and mechanism are needed.

### WE080

## Challenging plasticity: can acidified conditions alter susceptibility to emerging contaminants in marine bivalves at different life-stages?

M. Munari, University of Padova / Biology; V. Matozzo, University of Padova / Department of Biology; F. Gagne, Emerging Methods, Environment Canada / Emerging Methods; G. Chemello, V. Riedl, L. Finos, University of Padova; M.G. Marin, University of Padua / Department of Biology

Climate changes may alter marine organism susceptibility to pollutants, however this condition may be differently displayed in adult and early-life stages. To verify this hypothesis, the combined effects of seawater CO<sub>2</sub>-driven acidification and diclofenac (a non-steroidal anti-inflammatory drug, NSAID) were investigated in the Mediterranean mussel *Mytilus galloprovincialis* and the Manila clam *Ruditapes philippinarum*. Using a flow-through system, adult bivalves were acclimatized to three pH values (8.1, 7.7, 7.4) for 7 days. Thereafter, they were maintained for 14 days at the three pH values and simultaneously exposed to environmentally relevant concentrations of diclofenac (0, 0.05 and 0.5 µg/L). Haemocyte parameters (total haemocyte count, haemocyte volume and diameter, Neutral Red uptake, haemocyte proliferation and lysozyme activity) and oxidative stress parameters (superoxide dismutase, catalase and cyclooxygenase activities, lipid peroxidation and DNA strand-break formation) in gills and digestive gland were analyzed after 7, 14 and 21 days of exposure to the experimental conditions. Results showed that cellular and biochemical parameters measured were more influenced by pH than diclofenac with opposite patterns of variations between mussels and clams. *R. philippinarum* haemocytes showed reduced pinocytotic activity, compared to mussel haemocytes, suggesting a potential decrease in immunosurveillance. Despite cyclooxygenase (COX) is one of NSAIDs target, no significant effects due to diclofenac were revealed in this study, whereas pH significantly decreased COX activity in clams. Under flow-through conditions, fertilized eggs of *R. philippinarum* were exposed for 96h to two levels of pH (8.1 and 7.7) in the absence or presence of diclofenac (0.5 µg/L). Larval survival and growth showed to be significantly affected by both reduced pH and diclofenac; dramatic effects on shell development and prolapsed tissue outside the shell were observed in larvae kept at pH 7.7. The highest levels of catalase activity were detected in low pH/diclofenac treated larvae, indicating oxidative stress, even though no significant evidence of increased lipid peroxidation was found. Overall results highlighted that seawater acidification enhanced susceptibility of bivalve larvae but not of adults to environmental concentration of diclofenac, supporting the hypothesis that planktonic stages may be a population bottleneck under changing environmental conditions.

### WE081

**Combined impact of nutrition and pollution: the fatty acid profile modulates the tolerance to cadmium and methylmercury in fish**

A. Ferain, Institut des Sciences de la Vie; C. Bonneau, UCLouvain / Institut des Sciences de la Vie; I. Neefs, B. Lemaire, J. Rees, Université Catholique de Louvain / Institut des Sciences de la Vie; Y. Larondelle, UCLouvain / Institut des Sciences de la Vie; C. Debier, Institut des Sciences de la Vie Université catholique de Louvain

Aquatic organisms experience stress when an external stressor moves them away from their optimum performance in terms of growth and reproduction. For fish, sub-optimal nutrition and heavy metals exposure represent two frequent stressors. There is a good knowledge about responses of fish to these stressors when considered individually. The lipid quality of the diet ( $\omega$ -3 vs  $\omega$ -6 fatty acids (FA)) has considerable impacts on the lipid composition of the organism, the FA metabolism, the membrane fluidity and the susceptibility to oxidative stress. The contamination by heavy metals induces damages at both cell and organism levels (oxidative stress, altered membrane fluidity and FA metabolism, reduced growth and survival). Though both dietary lipid quality and heavy metals influence similar biological processes (e.g. redox homeostasis, FA metabolism), the interactions between these two parameters are poorly known in aquatic organisms. In that context, we aimed to explore the functional role of lipids in fish sensitivity to heavy metals (cadmium and mercury). First, an *in vitro* approach was conducted to assess whether the cellular FA profile has an impact on metal toxicity and to explore mechanisms behind such interactions. Practically, seven cell batches, from the rainbow trout liver cell line RTL-W1, differing in their FA profiles were developed by enriching the growth medium with specific FA. These modified cells were then challenged with cadmium or mercury. Two  $\omega$ -3 FA,  $\alpha$ -linolenic acid (ALA) and eicosapentaenoic acid (EPA) showed a particularly high protection against cadmium (EC<sub>50</sub> 3 times higher than in non-enriched cells) and methylmercury (EC<sub>50</sub> 4-4.5 times higher than in non-enriched cells) but none protected the cells against inorganic mercury. The FA profile of the cells would likely have influenced the cell tolerance to metals through modulating the membrane fluidity, the metal uptake and sequestration as well as the ability of restoring the oxidative balance and preventing apoptosis. Based on the *in vitro* results, the protective potential of ALA and EPA against heavy metals is being investigated in rainbow trout juveniles to validate our observations at a higher level of biological organization. Overall, this study highlights the importance of food quality (at least in terms of its FA composition) in fish response to chemical contamination and provides novel perspectives to interpret contrasting toxicity studies.

### WE082

**Salinity, pH and Arsenic effects on the biochemical responses of the manila clam *Venerupis philippinarum***

C.V. Silva; E. Figueira, CESAM University of Aveiro; L. Salamanca, Universitat de Alcalá; A. Almeida, Departamento de Biología; A. Moreira, CESAM Department of Biology; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; R. Freitas, Biology

Climate change is predicted to occur in the next years, including a decrease of seawater pH and salinity shifts. Due to this, geochemical changes in sediments are expected, such as the mobilization of metals and metalloids previously adsorbed to sediments, their organic and inorganic speciation and interaction with sediments, and consequently, the increase of elements in water and sediments. The contamination with metals and metalloids such as Arsenic (As) has been of great concern in marine and estuarine ecosystems, since they cause environmental deterioration of natural conditions affecting the inhabiting marine organisms. Among all aquatic organisms, bivalves can accumulate concentrations several times higher than those in water and sediment, due to their ability to filter large quantities of particles. *Venerupis philippinarum* has been used as a sentinel organism to assess the impact of pollution in different marine ecosystems, being a good candidate to provide relevant information on environmental changes. Therefore, the goal of this study was to study the ability of the invasive clam *V. philippinarum* to cope with a range of salinities (17, 28 and 42 g/L) and pH (7.8 and 7.3) that may occur under a climate change scenario, associated with the presence of environmentally relevant concentrations of As (0, 4 and 17 mg/L). Mortality and detoxification strategies such as total protein, lipid peroxidation, glutathione reduced and oxidized, antioxidant responses (catalase, superoxide dismutase activity) and detoxification mechanisms (glutathione-S-transferase) were determined in organisms exposed to different conditions (As, pH, salinity, and the combination of As with pH or salinity). The results obtained revealed that none of the conditions induced mortality. However, the LPO content increased with the increase of As exposure concentrations, both at control conditions (pH 7.8 and salinity 28) and when combined with low pH or salinities of 14 and 42. The catalase activity showed a similar pattern when combining As concentrations and pH. Nevertheless, the activity of this enzyme strongly decreased when organisms were exposed to salinity 42 and the combination of As and salinity 42. Overall, this species provided relevant information in the oxidative stress response to cope with changes in salinity and pH that may occur under climate change scenarios, associated with the presence of environmentally relevant concentrations of As in sediment.

#### WE083

##### Using sharks to address the impacts of ocean contamination: a multibiomarker approach

L.M. Alves; M. Nunes, LUNAM Université / Oniris Laboratoire d'Étude des Résidus et Contaminants dans les Aliments; N.A. da Costa, Polytechnic Institute of Leiria / ESTM GIRM; P. Marchand, B. Le Bizec, ONIRIS / LABERCA; S. Mendes, J. Correia, Polytechnic Institute of Leiria / ESTM GIRM; M.F. Lemos, Instituto Politécnico de Leiria / Dept Biology; S.C. Novais, Polytechnic Institute of Leiria / ESTM and GIRM

Marine ecosystems are constantly being loaded with contaminants like persistent organic pollutants (POPs) and heavy metals. Chemical analyses of pollutants provide information about contamination levels in the environment, but may not be sufficient to understand how organisms are being affected. There is a need to link these measurements with biological endpoints, for example through the assessment of enzymatic activities. Big pelagic apex predators, like the blue shark *Prionace glauca*, are particularly affected by pollution, mainly through bioaccumulation and biomagnification. Their large distributions, along with their abundance and frequent capture by commercial fishing boats, make them potentially good species for use in biomonitoring studies. This study aimed to assess the potential of *P. glauca* as a sentinel species for pollution monitoring surveys, using biochemical biomarkers. Twenty blue sharks were sampled of the coast of Portugal, aboard a commercial swordfishing boat. POPs concentrations and heavy metals, as well the levels of biochemical parameters related with detoxification, oxidative stress, energy metabolism and neuronal functions, were measured. As a first part of this study, the characterization of the cholinesterases (ChE) present in muscle and brain tissues of *P. glauca* was made to evaluate their potential for further biomonitoring studies. The results suggest that the brain seems to contain atypical ChE, presenting mixed properties of two ChE types whereas the muscle seems to contain mostly acetylcholinesterase. The *in vitro* exposure to a model pesticide showed that, the brain was the most sensitive tissue and therefore the most suitable for detection of exposure to low concentrations of anticholinergic compounds in the environment. This study indicates that ChE activity in blue sharks has the potential to be used as a sensitive and reliable biomarker in marine biomonitoring programs. POPs and heavy metals were found to be present at higher concentration in liver than in muscle. Both positive and negative correlations were found between physiological parameters and contaminant accumulation levels and some suitable biomarker candidates were identified. This study highlights the usefulness of biochemical parameters, when combined with pollutant body burden determinations, to assess effects of contaminants and demonstrates the great potential of *P. glauca* to be used as a sentinel of marine pollution, through the use of suitable biomarkers.

#### WE084

##### Effects of carbon nanotubes and interactions with silver and silver nanoparticles on early life of sea urchins: from strong cellular impairment to

##### effective cellular immune response.

A. Magesky, Université du Québec / ISMER Oceanography; E. Pelletier, University of Quebec, Rimouski / ISMERUQAR

Nowadays contamination driven by anthropogenic activities has been widespread over the world and has become another harmful factor that living organisms have to go through even in early life stages. Prevailing assumptions about carbon nanotubes behavior indicate that they could act as contaminants-carriers. Likewise, given the increasing applications and likelihood of silver nanoparticles releases into the aquatic systems, some attention has been attracted to deciphering their toxic effects. So far, however, there is a paucity of data on the comparative effects of mixtures of functionalized single-walled carbon nanotubes (fCNTs) with silver (Ag+fCNTs) and with organic-coated silver nanoparticles (NPPaam+fCNTs) on various stages of the development of marine invertebrates. Given these considerations, we chose the green sea urchin *S. droebachiensis* in early development to investigate the effects of silver, nanosilver and their mixtures with fCNTs. Thus, our experimental design included short-/long-term exposures and recovery. Four nominal concentrations of silver/nanosilver (500, 100, 50 and 20 µg/L) were combined with fCNTs (50, 10, 5, 2 µg/L). These experiments were performed taking into account the major events in embryogenesis (at 5°C), larval development and juvenile growth (both at 8°C). Microscopic observations were made *in vivo* by confocal microscopy. We also measured oxidative stress at 96h of exposure. Dissolved silver found in exposure medium was quantified by ICP-MS. Our results pointed towards a strong effect of silver toxicity held by fCNTs on all stages. This fact was also supported by higher levels of silver found in mixtures with fCNTs. Sublethal concentrations of Ag+fCNTs had a significant impact on mortality of embryos during recovery period. In contrast, NPPaam+fCNTs mixtures are less toxic than NPPaam and Ag+fCNTs. Whereas red spherule cells migrations and coelomocytes were strongly disrupted in embryos, both cells were able to repopulate rapidly to damages caused by chemical stress in larvae and juveniles. While NPPaam was more effective to slow down metamorphosis, Ag+ had a severe impact on mortality. Conversely, larvae exposed to both mixtures were never able to go forward with morphogenic changes. Taken together, these findings provide a more precise understanding of fCNTs effects to mobilize and transport different contaminants to animals and how this could impact marine invertebrate early life over time.

#### WE085

##### Comparison of different extraction methods for the determination of booster biocides in marine organisms through liquid chromatography-mass spectrometry.

L.R. Diniz, São Paulo State University- Institute of Chemistry; E.M. Vieira, Sao Paulo University / Departamento de Química e Física Molecular; T.C. Franco, Universidad Federal do Maranhão / Technological Chemistry; C. Afonso-Olivares, Universidad de Las Palmas de Gran Canaria; R. Guedes-Alonso, Universidad de Las Palmas de Gran Canaria / Chemistry; S. Montesdeoca-Esponda, Departamento de Química; M. Torres-Padrón, Z. Sosa-Ferrera, J. Santana-Rodríguez, Universidad de Las Palmas de Gran Canaria / Departamento de Química

Since restrictive regulation of the antifouling agent tributyltin, the study of alternatives for the use of tin free antifouling painting is increasing due to high level of contamination in the marine and coastal ecosystems. Around eighteen non-metallic organic compounds worldwide are currently used or promoted as agents in antifouling painting. Some of the most common booster biocides are 4-chloro-3-methylphenol, chlorothalonil, dichlofluanid, diuron, thiram and irgarol 1051 and some degradation product of irgarol 1051 like M1. Although they are less persistent in the environment, many of these compounds have been associated with noxious effects such as metabolic disorders, infertility and inhibition of growth, reduction in immunity and even death of some organisms [1]. There are a few studies related with the methods for determination of booster biocides in biological samples. Some studies have reported diuron, irgarol 1051 and M1 in tissues of marine algae and molluscs at level of ng g<sup>-1</sup> [2]. The use of soft tissue of clams may be a viable option for the chemical analysis of the presence of anti-fouling in port areas, considering reports of some studies on the cause-and-effect relationship between exposure to organotin antifouling and the development of imposex in *Stramonita haemastoma*, a mollusc often found in rocky shores, anatomically related species of the genus *Thais*, commonly found in tropical and temperate waters. Before that, it is necessary to develop a viable methodology to extract and determine booster biocides in these kind of matrices. In this work, we have optimized different extraction methods (sonication, microwave assisted extraction and liquid-liquid microextraction) coupled to liquid chromatography with mass detection to determine diuron and irgarol in molluscs. Results were compared to obtain the best analytical method to determine these booster biocides in soft tissues of this type of molluscs. #### WE086

##### Phenoxidase activity in wild mussels (*Mytilus galloprovincialis*) exposed to Fluoranthene under different nutritional conditions

D. Romero, University of Murcia / BiologyToxicology; C. González-Fernández, Spanish Institute of Oceanography / Marine ecosystems; J. Campillo, Instituto Español de Oceanografía; L. Vinas, Spanish Institute of Oceanography; J. Bellas, Centro Oceanográfico de Vigo / IEO (Instituto Español de Oceanografía); A. Franco, Instituto Español de Oceanografía; M. Albentosa, Instituto Español de Oceanografía / Centro Oceanográfico de Murcia

Xenobiotics produce important immunological disorders in marine organisms, as in the mussel, *M. galloprovincialis*. The study of these alterations in laboratory studies is really useful in order to identify biomarker responses of organisms to pollutants. Sensitivity of phenoloxidase activity (PO) to pollution suggests that this enzyme might be a reliable biomarker in monitoring programs. On the other hand, food availability in the environment seems to condition the biological responses to pollution at different organization levels. Therefore, environmental trophic conditions could affect the immune responses to pollution. The experiment was designed to determine the relative importance of these two environmental variables: food availability and the presence of toxicants, on PO activity. Three experimental trophic conditions were simulated by regulating daily food ration during 45 days: low food condition (N1), medium food condition (N2) and high food condition (N3), which promoted negative, maintenance and positive mussel energy balances, respectively. In all cases, mussels were exposed to two nominal fluoranthene (FLU) concentrations (3 and 60  $\mu\text{g L}^{-1}$ ) for 3 weeks. After that, mussel haemolymph was extracted and analyzed spectrophotometrically, quantifying the production of dopacrome from L-DOPA and using SDS as elicitor. Multifactorial ANOVA showed a significant effect of nutritive condition on PO activity being this activity higher in low condition mussels (N1). Contrary to expected results, PO activity did not show any significant effect of FLU exposure in any mussel condition which could suggest that the effect of mussel nutritional status is so important than can mask the effect of pollutants.

#### WE087

##### Fluoranthene toxicity in *Mytilus galloprovincialis* at different stages of gametogenesis measured by biochemical biomarkers

C. González-Fernández, Spanish Institute of Oceanography / Marine ecosystems; M. Albentosa, Instituto Español de Oceanografía / Centro Oceanográfico de Murcia; J. Campillo, Instituto Español de Oceanografía; L. Vinas, Spanish Institute of Oceanography; A. Franco, Instituto Español de Oceanografía; J. Bellas, Centro Oceanográfico de Vigo / IEO (Instituto Español de Oceanografía)

Mussels, such as *Mytilus galloprovincialis*, are extensively used as sentinel species of pollution in marine coastal monitoring programs. Due to the large seasonal and spatial variability of marine ecosystems, large scale monitoring programs have some difficulties in the assessment of the effect of pollution on organism's biological responses. It has been widely reported that biomarker responses show a seasonal pattern due to exogenous (food availability and temperature) and endogenous (gametogenesis) factors. Generally, gonadal development of *M. galloprovincialis* mussels takes place between late autumn and winter, until the beginning of the spring, when the gonad is completely ripe and spawning occurs. During late summer and early autumn, there is a reserve storage that will be used for the next gametogenesis. The aim of this study was to evaluate the effect of mussel reproductive status on their response to one polycyclic aromatic hydrocarbon (PAH): fluoranthene (FLU), measured by several biochemical biomarkers of exposure (superoxide-dismutase -SOD-, catalase -CAT-, glutation reductase -GR-, glutation peroxidase -GPx-, glutation-s-transferase -GST-) and damage (lipid peroxidation -LPO-). For that purpose, mussels of the same size and from the same sampling site were exposed to FLU at two different seasons: when the mussels were in resting time (October) and when the gonads were completely full (March). Exposure was carried out at two nominal FLU concentrations (4 and 80  $\mu\text{g L}^{-1}$ ) for 3 weeks. Biological characterization of mussels from a biochemical, histological and anatomical point of view was also performed. Two-factor ANOVA analyses showed a significant effect of mussel reproductive status on several biomarker responses (SOD, CAT and GPx), whereas FLU exposure only affected GPx response. Mussels showed higher values on biomarkers measured during gonadal maturation than during resting time. Since, in large-scale marine pollution monitoring programs, mussels display a wide range of reproductive status, even at the same sampling time, mussel reproductive status should be considered in order to carry out an accurate interpretation of biomarker results.

#### WE088

##### Effect of copper in the freshwater bivalve *Corbicula fluminea*: Biomarker responses under laboratory and field in a short exposure time.

E. Bonnail, University of Cadiz / ChemistryPhysics; L.M. Buruaem, São Paulo State University - UNESP Campus Experimental do Litoral Paulista; L.G. Morais, Universidade Estadual Paulista UNESP; G. Araujo, Universidade de Aveiro / Biologia; D. Abessa, Unesp / Marine Biology and Coastal Management; A.M. Sarmiento, University of Huelva / Department of Geodynamics and Palaeontology

Cu is one of the best conductor of heat and electricity; has important industrial applications, especially in a growing electric commerce. Its demand is forcing the re-opening of closure mines. This promotes movements in soils and changes in the neighbouring ecosystems. Hence there is an increasing need to understand the effects of their eventual release into different environmental compartments and the species within. The Ribeira de Iguape River Basin is receiving discharges rich in As, Ba, Cd, Pb, Cu, Cr and Zn from a Pb processing plant. Cu contents ranged

between 0.0039-0.0062  $\text{mg L}^{-1}$  in water and  $8.8 \pm 3.7 \text{ mg Kg}^{-1}$  in sediments. It is possible to assess the ecological health of a river by studying the sediment-water composition and the bioavailable form. In this polluted scenario, the introduced species *Corbicula fluminea* meet all the requirements to biomonitor the courses due to is a filter feeder in contact with sediment, sessile, able to survive under extreme conditions and can be found in the Ribeira. Up to date the ecotoxicological risk for non target organisms is sparsely documented, with the focus predominantly on the acute toxicity of magnified expectable environmental concentrations. Thus in a laboratory-based study the clam was chosen as a model to evaluate cellular effects of dissolved Cu (0.5, 1 and 2 ppm) over 7 days. Ditto, two sites from Iguape were chosen as affected mining scenarios: after the mining split (Sete Barras) and close to the estuary (Registro); a third "non-polluted" point used as negative control (Pereque). Biomarkers of oxidative stress (GST, GPx, GR), exposure (MTs, AcHe) and damage (LPO, DNA strand breaks) were quantified. Results identify significant effects on the biomarker responses compared to the reference site (24h). Statistical analyses showed some significant differences after 7 days into the positive control of 2 ppm for the whole battery of biomarkers, except for MTs. Oxidative stress and damage was observed after Cu doped water exposure with 1 ppm. However at the tested concentrations, the particles did not cause significant oxidative damage, what make suspect about hormesis under extreme exposure. DNA damage was observed after 1ppm Cu exposure. Under sediment exposure, GST and LPO generated the greater response. To sum up, biomarkers analyses show stronger responses under waterborne; this might be influenced by burrowing and feeding activities that mask the enzyme stress

#### WE089

##### Seasonal variability of antioxidant biomarkers in mussels *Mytilus galloprovincialis* from the Spanish N-NW coast.

J. Bellas, Centro Oceanográfico de Vigo / IEO (Instituto Español de Oceanografía); J.A. Campillo, Instituto Español de Oceanografía; C. González-Fernández, Spanish Institute of Oceanography / Marine ecosystems; M. Albentosa, Instituto Español de Oceanografía / Centro Oceanográfico de Murcia

Marine organisms are highly seasonal animals in relation to their physiology which depends, among other factors, on their annual cycle of reproduction. In bivalves, reproductive cycle is regulated by two main environmental factors: temperature and food availability. Specifically, bivalves are undergoing high variable environmental conditions. Integrated pollution monitoring carried out by the IEO along the N-NW coast of Spain has evidenced that the variability of the environmental conditions produce spatial differences in mussel condition which seems to mask the biomarker responses to pollution. Thus, there is a need to study the natural variability of biological responses used as pollution biomarkers at different seasons and in different habitats in order to establish an adequate link between chemical pollution and biological responses. This study aims to assess the natural variability of some biomarker responses on the mussel *Mytilus galloprovincialis* in 5 different sites from the Spanish Marine Pollution Monitoring Program which are differentiated in their natural ecology and their anthropogenic pressure. The potential influence of environmental and endogenous factors that can cause biomarker's seasonal fluctuations was examined. Biomarkers analyzed in this study are considered among the most useful biological tools applied in pollution monitoring programs, including exposure indicators (superoxide dismutase -SOD-, catalase -CAT-, glutathione reductase -GR-, glutathione peroxidase -GPx-, glutathione-s-transferase -GST-) and a damage indicator (lipid peroxidation -LPO-). Mussel biological characterization from a histological and anatomical point of view was also performed. Results evidenced that biomarkers were clearly influenced by the annual cycle (all of them were affected by the season) but also significant differences between sites were found in some biomarkers (GR and GST). Thus, not only environmental but also endogenous factors must be considered in monitoring programs in the study of biomarkers responses.

#### WE090

##### Development of a phototoxicity protocol applying passive dosing to support hazard assessment

J. Butler, ExxonMobil Biomedical Sciences, Inc / Environmental Toxicology and Chemistry Laboratory; D. Letinski, ExxonMobil Biomedical Sciences Inc; G.E. Bragin, ExxonMobil Biomedical Sciences, Inc. / Environmental Sciences Division; T. Parkerton, M. Lampi, ExxonMobil Biomedical Sciences, Inc.; A.D. Redman, Exxon Mobil Biomedical Sciences

Phototoxicity considerations in environmental risk assessment have been limited by the lack of standardized test protocols. As a result, non-comparable data generated using varying methodologies are difficult to use in support of hazard assessment. Further, the disappearance of test compounds through loss mechanisms, including photodegradation processes, results in variable, declining exposures that complicate interpretation of test results. In the present research passive dosing using silicone O-rings was applied to maintain constant aqueous exposures of pyrene, a model photoactive PAH, to juvenile *Danio rerio* and *Ceriodaphnia dubia*. Exposures were conducted over 96 hours (*D. rerio*) or 7-days (*C. dubia*) with 12:12 hour light:dark cycles that included lighting from UV and fluorescent bulbs. For each test organism, pyrene exposures were performed at two aqueous concentrations and four light treatments (dark, low, medium and high UV light intensities, from 70 to 450  $\mu\text{Wcm}^{-2}$ ). Light intensities included spectra from UVA (320-400 nm) and photosynthetically active radiation (PAR 400-700 nm). For

zebrafish embryo exposures, some sublethal side effects (e.g., edemas) were observed though survival was found to be the most sensitive endpoint. Mortality for zebrafish embryos coincided with hatching, suggesting the chorion provided some level of protection from UVA. Effect concentrations for UVA irradiated tests in both species tested were greater than an order of magnitude lower than exposures in the dark. Residue analysis at study termination indicated that observed effects were inversely related to measured pyrene concentrations in test organism tissues indicating photo-transformation of accumulated pyrene contributed to the toxicity observed. The application of passive dosing in test design to maintain targeted, constant exposure concentrations provides an improved basis for developing consistent hazard data for phototoxicity test endpoints and subsequent model development to address interactions of chemical exposures and UV light in risk assessments.

#### WE091

##### **Effects of nutritional stress on the freshwater detritivore, *Gammarus fossarum*: looking at the molecular level**

**B. SOHM**, J. Arce-funck, C. Crenier, LIEC Université de Lorraine CNRS; M. Danger, LIEC; C. Cossu-Leguille, Laboratory LIEBE - CNRS UMR 7146 - Université de Lorraine; B. Xuereb, University of Le Havre; S. Devin, LIEC - Université de Lorraine - CNRS / LIEC CNRS UMR; F. Guerold, Université de Lorraine / Laboratoire Interdisciplinaire des Environnements Continentaux; V. Felten, LIEC

Nutritional constraints such as deficiencies in essential elements (e.g. nitrogen, phosphorus (P)) or molecules (e.g. essential fatty acids) impact living organisms at different levels from their growth, reproduction, energy storage to their response to biotic and abiotic stressors (contaminants). In forested headwater streams, mainly oligotrophic ecosystems, organisms are often subjected to low quality resources (i.e. P deficiencies). In such ecosystems, the detritivorous *Gammarus fossarum* represents a useful biological model as it plays a major role in leaf litter breakdown and is an important food resource for various predators. Gammarids have already been shown to be negatively impacted (survival and growth rate) by a lack of phosphorus in leaf litter. Yet, underlying mechanisms are still unclear and an investigation at the molecular level should help to decipher these effects. In this study, we submitted *G. fossarum* to different litters (2 litter species along a P gradient) and monitored their physiological and molecular responses (gene expression: mRNA analyses by RT quantitative PCR; proteins: western blotting techniques). Genes and proteins were selected according to their involvement in different metabolic pathway and sequence or antibody availability. We first showed that diet P deficiency is correlated with a significant drop in energetic compounds (glycogen, total lipids), directly impacting the locomotor activity of *G. fossarum*. At the molecular level, when fed with high P resources, *G. fossarum* also exhibited two upregulated mRNA. Interestingly, these genes encode proteins involved in ATP synthesis (ATP synthase sub-unit) and in nucleotides phosphate exchange to maintain equilibrium between the concentrations of different nucleoside triphosphates. Both proteins are implicated in high P content compounds production and their gene expressions were correlated with P content increase, suggesting that gammarids can use P to store energy (ATP for lipogenesis and glycogenesis). Identification of deregulated proteins by western blot is still ongoing. We argue that molecular tools will permit to go deeper in the knowledge of metabolism and regulation pathways of living organism in response to environmental stressors. In particular, it should permit to investigate in more details the physiological state of organisms and help disentangling the impacts of multiple stressors on organisms (e.g., nutrient and contaminant).

#### WE092

##### **Non-lethal heat shock increases tolerance to metal exposure in brine shrimp.**

**J.L. Pestana**, CESAM & University of Aveiro / Department of Biology and CESAM; S.C. Novais, Polytechnic Institute of Leiria / ESTM and GIRM; P. Norouzitalab, Ghent University / Laboratory of Aquaculture Artemia Reference Center Faculty of Bioscience Engineering Rozier Gent Belgium; M.B. Vandegehuchte, Ghent University / Laboratory of Environmental Toxicology and Aquatic Ecology; P. Bossier, Ghent University / Laboratory of Aquaculture Artemia Reference Center Faculty of Bioscience Engineering; K.A. De Schamphelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit  
Ecotoxicologists have been putting great efforts in methods to assess the ecological effects of complex mixtures to evaluate the environmental risk of contaminants under ecologically relevant scenarios of exposure. However, exposure to different stressors is not always simultaneous and evaluating the effects of sequential exposures is challenging. Besides the difficulties in modeling time–concentration–response relationships we should also consider the potential effects that initial exposure to one stressor might have on the tolerance of organisms to additional stressors, i.e., stressor induced co-tolerance. In recent years researchers have focused on non-lethal heat shock (NLHS) and how it is involved in cross-tolerance in different organisms. This is because heat shock proteins (Hsp's), acting as molecular chaperones, are induced and thought to protect organisms against different environmental stressors such as contaminants or pathogens and may be involved in the mechanisms of co-tolerance. However, there is limited information on the effect of NLHS on the subsequent tolerance of organisms to chemical exposure. Using gnotobiotic cultures of the brine shrimp *Artemia franciscana* we

investigated: a) if NLHS causes an increased tolerance to subsequent metal exposure (Cadmium and Zinc); b) if this co-tolerance is related to levels of 70kDa-Hsp's production and c) since both stressors have been shown to have epigenetic effects in crustaceans, we further investigated the possible epigenetic alterations (Dna methylation, histone acetylation) in *A. franciscana* exposed to non-lethal heat shock and metals. Our results show that exposing *A. franciscana* to a single NLHS (37 °C, for 30 min followed by 6 h recovery) markedly increased Cd and Zn tolerance. Moreover we observed that both NLHS and metal exposure increased in the production of Hsp70, with *Artemia* exposed to both stressors showing the highest levels of Hsp's. However, and concerning the epigenetic markers, we could not observe any effects of NLHS nor of metal exposure on DNA methylation or histone acetylation in the first 12h of exposure. In sum, we have shown that NLHS can induce tolerance to subsequent metal exposure with some evidences for the possible protective role of Hsp's against both stressors. This work highlights the challenges of evaluating ecological effects of sequential exposures and call for discussion on the relevance and ubiquity of stressor induced co-tolerance.

##### **The immunotoxic effects of Deepwater Horizon oil on Gulf of Mexico fish species**

**R. Takeshita**,

In support of the *Deepwater Horizon* (DWH) Natural Resource Damage Assessment, we conducted a series of laboratory tests to investigate the immunotoxic effects of DWH oil on fish species from the northern Gulf of Mexico. Juvenile red snapper, southern flounder, Atlantic croaker, and red drum were exposed to oil via water accommodated fractions or spiked sediment for 2-9 days. During the oil exposure, we performed a bacterial challenge by moving the animals to tanks of seawater inoculated with *Vibrio anguillarum* (10<sup>6</sup> cfu/ml) for one hour. Fish were then monitored over time for mortality and behavior, and a subset of live animals were sacrificed for analysis at various timepoints post-bacterial challenge. Depending on the species, we measured growth (length and weight), red blood cell counts, gene expression, and microbiome composition. Our data analysis is ongoing, but our preliminary results demonstrate a dose-dependent immunosuppressive trend—from the molecular to organismal levels—in animals exposed to DWH oil.

#### WE094

##### **Assessment of the genotoxicity and mutagenicity of hydric resources related with petroleum refining activities**

**M. Hoshina**, Unesp - Institute of Biology / Biology; M.A. Marin-Morales, UNIVERSIDADE ESTADUAL PAULISTA - UNESP / Department of Biology  
Technological advances have many benefits; however they are accompanied by an increase in the emission of effluents derived from several types of anthropogenic activities, which generally generate undesirable by-products that can carry several chemical contaminants that are discharged into the environment. Petroleum refining industries, in particular, produce effluents rich in organic and inorganic compounds such as polycyclic aromatic hydrocarbons (HPA) and metallic compounds. These substances present in the petroleum are associated with the increased incidence of several types of alterations in the living organisms. The present study aimed to assess the genotoxicity and mutagenicity of waters of the rivers Jaguari, Atibaia and Piracicaba in a region under the influence of a petroleum refinery located in the municipality of Paulínia – SP, Brazil. The comet assay and micronucleus test were performed both in the fish species *Oreochromis niloticus* and with human hepatoma cells (HepG2) maintained in culture, in three different seasons of the year, winter 2013, summer 2014 and autumn 2014. From the results obtained, we could observe that the waters of the rivers analyzed, as well the refinery effluent, presented genotoxic and mutagenic potential. These potential can be related with pollution from anthropic origin, case of Jaguari River, where the main source os pollutants would be domestic effluents and for the Atibaia and Piracicaba rivers that are impacted by domestic and industrial effluents. We also observed that after the discharge of the petroleum refinery into the Atibaia River there was an increase in the genotoxicity and mutagenicity of this river, indicating that the effluent can interfere in the quality of the river. From the analyses of the results we verified that there is influence of seasonality in these biological effects, and the genotoxic (for both test systems) were more pronounced in the summer and the mutagenic in the winter.

#### WE095

##### **Thermal history, heat shock and metal toxicity tolerance in the zebrafish (*Danio rerio*)**

**A. Pilehvar**, Antwerp university / Biology; R. Blust, University of Antwerp / Systemic Physiological and Ecotoxicological Research Department of Biology  
Zebrafish have become one of the most important animal models in biological research including ecotoxicology. Although there are several studies in literature on the metal uptake and toxicity in zebrafish, investigation on the interaction between thermal background of the organism and metal uptake and toxicity are rare. The aim of our study is to examine the effect of thermal acclimation and sub-lethal heat shock (in long and short intervals) on the metal uptake and toxicity in adult zebrafish. Different temperature shocks (32°C and 34°C) were applied to the fish and they were subsequently exposed to the metal contaminated water containing

Cu, Cd or Cu+Cd. The condition of the fish was monitored for 10 days, including behavioural and physiological metrics and also water quality monitoring (ammonia concentrations, metal analysis etc.). At the end of the exposure period, whole body and tissue metal concentrations were determined (i.e. brain, gills, liver, gut and muscle). The results showed that the fish which were exposed to the Cu were more sensitive than the ones exposed to Cd. Moreover, the toxicity in the Cu+Cd exposure was much higher than expected. The sensitivity of the fish to metal exposure depended on the thermal prehistory of the fish, the physiologically optimal temperature range (26–28°C) was neither the most metal sensitive nor tolerant acclimation temperature. A 32°C heat shock significantly improved tolerance against single and mixture metal toxicity compared to the ones not shocked or shocked at 34°C. The results also showed that short shock intervals leads to better tolerance against toxicity of metal mixtures. The results of these experiments show that the thermal prehistory and exposure temperature play an important role in determining the tolerance of zebrafish towards metal exposure. Heat shock treatment increases the tolerance but both the applied temperature and duration of the heat shock are critical in determining the final impact on metal tolerance. The observed effects are only partially related to the effect of temperature on metal uptake and accumulation and indicate that temperature acclimation and heat shock treatment result in homeostatic adjustments and up-regulation of certain defence system that also have an impact on metal tolerance. Analysis of gene expression and protein profiles is underway to reveal the molecular physiology that may provide explanations for the effects observed at the organismal level.

#### WE096

##### **Chemical contaminants and biomarker responses in caged and native mussels (*Mytilus trossulus*) in the Archipelago Sea (SW Finland, Baltic Sea)**

K.K. Lehtonen, Finnish Environment Institute / Marine Research Centre; R. Turja, Finnish Environment Institute, SYKE / Marine Research Centre; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC; M. Dévier, LPTC-EPOC, University of Bordeaux / Oceanic and Continental Environments and Palaeoenvironments

Mussels (*Mytilus trossulus*) were transplanted in cages along a suspected pollution gradient in the inner Archipelago Sea (SW Finland), northern Baltic Sea. The mussels were retrieved in early July and late August, 71 and 121 d from the start of the experiment for the measurement of tissue concentrations of chemical contaminants (polycyclic aromatic hydrocarbons [PAH], organotin, organochlorines, brominated flame retardants and trace metals) and a suite of biological endpoints including biomarkers (acetylcholinesterase activity, oxidative defence enzymes and metallothionein) and growth related parameters. Additional seasonal samples were collected from a mussel population at an alleged reference site. In spring the mussels showed markedly elevated tissue concentrations of numerous contaminants (e.g., PAH), apparently due to loss of tissue mass during the long winter period, and also higher levels of various biomarkers responses (e.g., glutathione *S*-transferase activity). Marked differences in the accumulation of contaminants and biological variables were recorded between the caging sites, confirming the alleged contamination gradient. Aggregation and multivariate analysis methods over the biological effects data were able to distinguish the different caging sites from each other with linkages to the measured contaminant profiles. Temporal changes in the accumulation of contaminants and biological parameters were also observed, some of them (e.g., growth) being related to seasonal changes in prevailing environmental factors such as temperature and food availability. The results underline the importance of understanding the effect of seasonal natural factors on the general condition and growth dynamics of mussels when assessing tissue concentrations of chemical contaminants and biological effects. The study supports the use of caged organisms in environmental monitoring and assessment of marine pollution in the Baltic Sea.

#### WE097

##### **Impact of metal stressors between the polychaete "*Branchipolynoe seepensis*" and the host mussel "*Bathymodiolus azoricus*" from Mid-Atlantic-Ridge hydrothermal vents**

C. Cardoso, Institute of Marine Research CIMA-University of Algarve / IMARDOPCIMAUA; T. Gomes, Norwegian Institute for Water Research (NIVA); J. Blasco, Inst. Ciencias Marinas de Andalucía / Instituto de Ciencias Marinas de Andalucía; A. Colaco, University of Azores / IMARDOP; R. Serrão Santos, IMAR Institute of Marine Research MARE Marine and Environmental Sciences Centre; M. Bebianno, University of Algarve  
Hydrothermal vents are extreme environments with a variety of specific conditions that rendered them as one of the most productive and biology-rich deep-sea ecosystems. The fluids emanated from the sea floor are nutrient-rich with high metal concentration that supports food web based on chemoautotrophic primary production. The vent commensal polychaete *Branchipolynoe seepensis* is commonly found in the pallial cavity of the vent mussel *Bathymodiolus azoricus*, the dominant species along the Mid-Atlantic-Ridge (MAR). These vent worms have the ability to accumulate high levels of metals in their body absorbed from the surface of mussel gills. Mussels *B. azoricus* were collected from two sites from Lucky Strike Hydrothermal vent (1700m), Montségar-MS and Eiffel Tower-ET and from Rainbow hydrothermal vent (2300m) and checked for the presence of *B. seepensis*. Furthermore, to compare the interaction between both species, mussels were collected from Menez Gwen hydrothermal vent (MG2, MG3 and MG4)

(850m) where polychaetes don't exist. Metal concentrations (Ag, Cd, Co, Cu, Fe, Mn, Ni and Zn) were determined by ICP-OES in total and subcellular fractions of mussel tissues (gills, digestive gland and mantle) and in polychaetes whole body. Biomarkers of metal exposure, metallothioneins (MTs), and oxidative stress, namely antioxidant defence enzymes (catalase (CAT) and glutathione-*S*-transferase (GST)) and lipid peroxidation (LPO) were also determined in both species. Results showed different metal concentrations in polychaetes and mussels tissues in both fractions, suggesting inter- and intra-variation of vent chemistry between hydrothermal fields. In general, metal concentrations were higher in polychaetes insoluble fraction and soluble heat-stable fraction from ET and MS, respectively, and in mussel gills, followed by mantle and digestive gland, excepting for Fe, Co and Ni. In addition, MT and LPO were higher in polychaetes from Rainbow and MS vent sites and in mussels higher in gills followed by the digestive gland and mantle in the three vent fields. Mussels had higher levels of CAT in digestive gland, followed by gills and mantle and while GST levels were higher in gills followed by digestive gland. In polychaetes the tendency of CAT and GST was similar, with higher levels in ET. Overall, the presence of the commensal polychaete *B. seepensis* in pallial cavity of *B. azoricus* seems to be an adaptation to the elevated metal concentrations near vent sites.

#### WE098

##### **Temperature influences gene expression and phenanthrene effects in biotransformation system of *Crassostrea brasiliana***

D.d. Lima, UFSC; F.L. Zacchi, J.J. Mattos, Universidade Federal de Santa Catarina / Bioquímica; C.L. Bastolla, I.M. Reis, G.d. Müller, R.S. Piazza, C.E. Piazza, F. Flores-Nunes, M.A. Serrano, C. Pessoa de Mello, Federal University of Santa Catarina; A.C. Bainy, Universidade Federal de Santa Catarina / Bioquímica  
In poikilothermic organisms, such as bivalves, ambient temperature is one of the major factors driving physiological and biochemical processes. Nowadays, global warming is an emerging threat to ecosystems, and there is a need to investigate the biological responses to short-term enhance in seawater temperature as future climate scenarios. Mangrove oyster (*Crassostrea brasiliana*) is a sentinel organism extensively used in environmental monitoring. The aim of this study was to evaluate the effect of temperature on the responses of oysters to phenanthrene exposure. The oysters were exposed to phenanthrene 100 Åg/L for 24 and 96h at 18°C, 24°C and 32°C under controlled laboratory conditions. A control group, without phenanthrene, was kept at each temperature. The levels of phenanthrene in the water was monitored by fluorescence at 250 nm excitation/360 nm emission in the first 24h. Two-way ANOVA was carried out to evaluate the effects of temperature and time of exposure ( $p < 0.05$  was considered significant). The half-life of phenanthrene in water was inversely related (4.9h in 18°C; 2.1h in 24°C and 1.7h in 32°C). This result may indicate an increase in oyster metabolism, in higher temperatures, which increases the filtration rate. It was also investigated the relative levels of gene transcripts in the gill from control and exposed oysters by qRT-PCR. After 24h of exposure, gill cytochrome P450 (*CYP2-like*) from the exposed group at 24°C was significantly higher than the control group. It was seen interaction between phenanthrene and temperature, since control groups of 24°C and 32°C were significantly lower when compared to the control of 18°C. Similar pattern is observed in the 96h groups, however, there are no differences between control and phenanthrene groups. Glutathione *S*-transferase (*GST omega-like*) and Fatty acid binding protein (*FABP-like*) showed differences between control groups of 18°C and 24°C, after 24h exposure. Superoxide dismutase (*SOD-like*), in 96h also showed differences between control groups of 18°C and 24°C and 32°C. *GST microsomal-like*, *sulfotransferase (SULT 1C1-like)*, Glutathione peroxidase (*GPx-like*) and *catalase (CAT-like)* did not show differences. These results show that temperature by itself affect some of the tested genes and the response to phenanthrene exposure.

#### WE099

##### **Accumulation of trace elements in liver and muscle: similarities and differences in *Platichthys flesus*, *Solea solea* and *Dicentrarchus labrax* from two estuaries in Portugal**

O. Araujo, DIVOA; P. Pereira, Department of Biology and CESAM; M. Caetano, IPMA I.P.; C. Vale, IPMA Instituto Portugues do Mar e da Atmosfera; J.M. Neto, University of Coimbra / Marine and Environmental Sciences Centre; J. Lino Costa, Universidade de Lisboa / Instituto de Oceanografia; J. Raimundo, IPMA / DIVOA  
Estuaries are important ecosystems due to their services and biodiversity. The presence of human pressures in the margins and watershed, often affects the Ecological Status of the system. Metals and metalloids are of particular concern due to their persistency in tissues of aquatic organisms. Despite the mobility of fishes in estuaries, accumulated toxic elements in liver and muscle may reflect availability in environment as well as biochemical processes. Sixty two juvenile specimens of *Platichthys flesus*, *Solea solea* and *Dicentrarchus labrax* were obtained in two Portuguese estuaries (Mondego and Mira) of similar typology. Individuals were captured along the estuaries in winter and summer of 2012, and essential (Zn and Cu) and non-essential elements (As, Cd and Pb) were determined in muscle and liver. Differences on trace element accumulation were investigated in specimens showing no significant differences on the biometric parameters weight, length and Fulton's index condition. Results pointed to a lower accumulation of Zn and As in liver than muscle, while higher contrast was found for Cu, Pb and Cd reflecting the capacity of liver to retain these elements. Accordingly, no significant differences

were found for Zn concentrations in specimens between Mondego and Mira, maybe due to the essentiality of this element. *Platichthys flesus* and *D. labrax* from Mondego exhibited higher concentrations of Cu (muscle) and As (muscle and liver) than from Mira. Those geographical differences were not observed in *S. solea*. A clearer geographical pattern was obtained for Cd, showing higher concentration in liver of *P. flesus*, *D. labrax* and *S. solea* from Mira than from Mondego. The lack of differences in muscle reinforces the role of liver on Cd detoxification.

#### WE100

##### **Measurements of cardiac activity and markers of oxidative stress in gills of freshwater bivalves *Anodonta cygnea* L. exposed to a short-term salinity change used as functional load**

T. Kuznetsova, Saint-Petersburg Scientific Research Center for Ecological Safety Russian Academy of Sciences / LabBioelectronic Methods for Geoecological Monitoring; A. Sharov, Russian Academy of Sciences / Institute of Biology of Inland Waters; S. Kholodkevich, Russian Academy of Sciences / Saint-Petersburg Scientific Research Center for Ecological Safety; G. Chuiko, D. Pesnia, Russian Academy of Sciences / Institute of Biology of Inland Waters

The present study was carried out to assess the water salinity change as a form of standardized functional load for evaluation of physiological state of freshwater organisms. In this frame two different approaches were used simultaneously: a non-invasive cardiac activity monitoring and measurements of biochemical markers of oxidative stress (OS) in gills of freshwater bivalves *Anodonta cygnea* Linn. Bivalves were exposed in laboratory to saline solution of sodium chloride at a concentration of 3 ppm for 60-120 min and then the salt water was replaced by fresh water. Cardiac compensatory response to such type of load and dynamic of heart rate (HR) after replacement of water to natural one were registered by on-line heart rate monitoring system simultaneously in 8 mollusks. Exposure caused increase in HR of bivalves from the beginning of the salinity change and during all the time of exposure. Replacement of salt water by ambient one caused recovery of HRs in 1-2 hrs according to bivalves' physiological state. Exposure of bivalves to saline solution did not cause any changes in the content of malonic dialdehyde (MDA), a lipid peroxidation (LPO) products, reduced glutathione (GSH) and activities of catalase (CAT), glutathione reductase (GR) and glutathione-S-transferase (GST). However, when saline solution after exposure of 60 and 120 min was replaced by fresh water, significant increase of MDA was revealed after 15-min recovery period. Simultaneously induction of activities of CAT and GST were reported. After 45-60 min of recovery these parameters returned to normal levels and were not changed till the end of the experiment. At the same time, GSH content and GR activity was significantly increased after 120 min in bivalves after recovery to ambient freshwater. These results indicate that a short-term increase in water salinity to 3 ppm for 120 min doesn't induce OS state in gills of bivalves. However, returning bivalves to fresh water induces LPO and activates the antioxidant defense system in their gills. As a whole, changes of markers of OS were not great and quickly return to normal after an hour of salinity recovery. This study proves that a short-term osmotic stress (as a result of change in the salinity of medium) don't pose threat for this species of bivalves and could be used as a functional load to evaluate physiological state of the organism of hydrobionts.

#### WE101

##### **The *Dreissena polymorpha* invasion in Europe: the scale of the problem and a novel control strategy.**

S. Meehan, TSGE Consulting; A. Shannon, TSGE; F. Lucy, The Institute of Technology Sligo

Highly invasive zebra mussels (*Dreissena polymorpha*) in European freshwaters have rapidly spread to lakes, rivers and canals. Colonisation has been on natural substrates, freshwater biota and man-made infrastructure. The availability of an effective, yet targeted, mussel control product to replace those currently used (such as chlorine and other non-specific biocides) is urgently needed to mitigate mussel fouling impacts in drinking water plants and other facilities which are immersed or use fresh water resources. The efficacy of a naturally occurring soil bacteria, *Pseudomonas fluorescens* CL 145A, in controlling *D. polymorpha* was first demonstrated by Dr. Dan Molloy, formerly of the New York State Museum. Initial tests by Molloy showed that *Pseudomonas fluorescens* CL 145A is highly specific to the zebra mussel. Non target testing was carried out to further evaluate the specificity of CL 145A cells with respect to other common biota in European freshwater systems. This included protected and known vulnerable species in order to establish the potential for any impacts on native aquatic vertebrates and invertebrates. Two field trials were conducted to demonstrate the efficacy of CL 145A in industrial facilities (using onsite 'bioboxes' at a water treatment plant) and in infested open water (a canal). Effects on water quality during and after treatment were also monitored. Both trials achieved high levels of zebra mussel control (up to 81% adult mortality) and provided insights into practical application and possible control techniques. No long term effects on water quality were observed. This research demonstrates the potential to replace traditional control methods (for example as off label use of chemicals such as chlorine) with targeted novel biological biocides, thus helping to reduce the impact of *D. polymorpha* in the environment while protecting vulnerable native aquatic species. Keywords: Zebra mussel, invasive species control, biological biocide

#### WE102

##### **Methodology approach using effect-based monitoring tools to link surface water quality, ecotoxicity and pollutants availability**

N. Roig, Universitat Rovira i Virgili; J. Sierra, Universitat Rovira i Virgili / Soil Science Unit; I. Moreno Garrido, Instituto de Ciencias Marinas de Andalucía (CSIC); E. NIETO, INSTITUTE FOR MARINE SCIENCE OF ANDALUSIA ICMANCSIC / ECOLOGY AND COASTAL MANAGEMENT; M. Hampel, Instituto de Ciencias Marinas de Andalucía CSIC / Consejo Superior de Investigaciones Científicas; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health; J. Blasco, Inst. Ciencias Marinas de Andalucía / Instituto de Ciencias Marinas de Andalucía; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering

According to the European Water Framework Directive, the assessment of the ecological status of freshwater systems is based on biological, physicochemical and hydromorphological quality. Some studies have observed that biological status is not always in coherence with chemical status, maybe due to the adaptation mechanisms of aquatic organisms under chronic chemical exposure. In these situations, ecotoxicity tests could be useful to resolve these divergences. The use of effect-based monitoring tools has been mentioned in the context on the Common Implementation Strategy (CSI) focused on regulated substances, which involves that many substances are not considered and their contributions to toxicity are lacking. The general aim of this study is to design a methodology to categorize the ecotoxicological status of rivers. The specific aims are: to compare the effectiveness of different ecotoxicity tests performed with freshwater sediments; to evaluate the relation between ecological status, pollutant content, their bioavailability, and water and sediment ecotoxicity; and to develop a general methodology to evaluate the relative contribution of the main pollutants to the toxicity in order to improve management tools. Two sampling campaigns were carried out in 2013 and 2014 within the Ebro River (Spain) watershed. Thirteen composite samples of sediments were collected and data on the chemical and ecological status has been achieved. The ecotoxicity of pore water and whole sediments was evaluated by *Vibrio fischeri*, *Nitzschia palea*, *Pseudokirchneriella subcapitata*, *Daphnia magna* and *Chironomus riparius*. In addition, the trace metals bioavailability was calculated by a sequential extraction according to the BCR method. To distinguish the potentially toxic fraction associated to trace metals burden of sediments, an analysis of acid-volatile sulphide and simultaneously extracted metals was performed. The results indicate that the ecotoxicological approach in most of the analyzed sediments is in agreement with their ecological status. This study demonstrates that the integration of chemical, biological and ecotoxicological analyses could be crucial to understand the hazard of pollutants in aquatic ecosystems, especially, in freshwater sediments. Moreover, it corroborates that cost-effective and rapid screening short-term bioassays could be useful to determine the surface water ecotoxicological status.

#### WE103

##### **Spatial hotspots for the introduction of crop plant residues into surface water bodies - a procedure for stream type prioritization**

R. Bundschuh, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; U. Kuhn, TIEM Integrierte Umweltüberwachung GbR / Büro Kuhn; C. Naegel, University Koblenz Landau / Institute for Environmental Sciences; D. Elsaesser, University of Koblenz; M. Bundschuh, Department of Aquatic Sciences and Assessment Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment; S. Ulrich, TIEM Integrierte Umweltüberwachung GbR; B. Oehen, A. Hilbeck, Swiss Federal Institute of Technology / Institute of Integrative Biology; R. Schulz, University of Koblenz-Landau / Institute for Environmental Sciences; M. Otto, Federal Agency for Nature Conservation; F. Hofmann, TIEM Integrierte Umweltüberwachung GbR / Ökologiebüro Hofmann

Genetically modified (GM) plants are, not only in the United States but also in European countries, marketed as an integrated package of various pest and disease prevention and control measures. GM plants are resistant for instance against insect pests by the production of Bt-proteins, and their environmental impact is controversially debated. Irrespective of the ongoing debate, GM plants represent a new challenge for the environmental risk assessment since the active substances can be introduced into aquatic ecosystems via plant residues and may cause adverse effects on aquatic organisms ingesting of this plant material as food. However, this particular exposure pattern is not properly reflected by the traditional pesticide risk assessment procedures that mainly focus on the water phase or sediment. The identification of the ecosystem types that potentially receive large amounts of plant residues following harvest seems a sensible first step in the prioritisation of risk assessment efforts. In this context, we suggest a method, which may be used to prioritise the risk assessment efforts for aquatic ecosystems, which may receive GM crop residues. By combining data of the European Water Framework Directive (WFD) on the stream network in Germany, with regionalized data on the cropping density of our model crop corn, the potential exposure of stream types could be identified and visualised in detailed spatial resolution using geographic information systems. For the assessment, several exposure indices were calculated such as the exposure factor, the intensity and its frequency for each stream type. For the identification of stream types that may be particularly vulnerable to the introduction of large amounts of crop residues, stream type specific sensitivity was estimated by the frequency of water bodies with an at least good ecological status as defined by the WFD. By combining all these indices in a selection matrix the information lead

to a prioritization of potentially most exposed and sensitive stream types. The suggested procedure should support the authorities by identifying potentially exposed and sensitive habitats and species living in these habitats that may be particularly vulnerable to GM exposure.

#### WE104

##### **Photo-Induced Toxicity of Deepwater Horizon Oil to Native Gulf of Mexico Fish and Invertebrate Species**

J.M. Morris, Stratus Consulting; A.P. Roberts, University of North Texas; J. Oris, Miami University / Department of Biology; C. Lay, Stratus Consulting; J. Lipton, Stratus Consulting, Inc.

In support of the *Deepwater Horizon* (DWH) Natural Resource Damage Assessment, we have conducted over 50 bioassays and related chemical characterizations to determine the photo-induced toxicity of DWH oil to native species in the Gulf of Mexico. Several tests combining waterborne or sediment exposures of early life stage organisms to oil followed by exposure to natural sunlight were conducted on 10 different species of fish and invertebrates. These tests included a range of life stages spanning from gamete exposures to exposures of gravid females. Exposure to UV light following oil exposure generally increases the toxicity of the oil by at least 10 fold during very short duration experiments (1-24 h). Analyses of these data are ongoing but we will discuss effects levels for a range of species including oysters, fiddler crabs, blue crabs, mahi-mahi, red drum, speckled sea trout and minnows. Additionally, we will discuss exposure chemistry, testing methods, and our meta-analysis of this dataset.

#### WE105

##### **Survey and Analysis of Data Available About the Water Quality of Micro Basin Lagoas in IlhaSolteira - SP, Brazil**

J.N. Oliveira, Unesp / Civil Engineering; K.T. Zambrano, Unesp / Civil Engineering Dept

The rapid human growth, without proper planning about the use and occupation of land, generate environmental impacts related to erosion, siltation and overload of water resources located in urban and peri-urban area of the city, compromising the water quality. Although, at world level, Brazil is a privileged country due to its large availability of water resources, many regions have water shortage problems that highlight the importance of sustainable management and preservation, especially in urban streams – victims of the growing population and misuse of resources – that suffers with the increasing flow and removal of riparian vegetation. In view of this, the survey and analysis of data about water quality of the micro basin Lagoas, located in the municipality of IlhaSolteira, northwest of São Paulo, allow studies concerning the magnitude of potential impacts in the last decade in order to conjecture steps to prevent them from propagating. A survey of published researches about studies on water quality was performed on the bank of dissertations from the Faculty of Engineering of IlhaSolteira. The search made used as keyword 'Stream', without a base year definition and resulted in 27 studies. Then, based on the studies reading, a new selection led to the identification of three dissertations about the subject. The authors considered a total of 8 study points in the micro basin, and analyses cover the period from 2002 to 2013. In general, in 2002 the closest points to urban areas showed elevated concentrations of turbidity, apparent color, solids, coliforms and BOD, as well as low levels of dissolved oxygen (DO), and most of the results disagree with the CONAMA Resolution. In 2011 was observed a significant increase in turbidity and solids parameters, as well as reduced levels of DO. In 2013, the parameters are still in disagreement with the Resolution and evidence the resource contamination and increase of erosion processes. This analysis emphasizes the need of measures such as the implementation of retention watersheds, improvements in use and conservation of the soil through techniques as management of level curves, clandestine sewage elimination, recovery of riparian forests and environmental education of society, in order to avoid permanent impairment of the watersheds water resources, that make impracticable the use and bring risks for health of the riparian population.

#### WE106

##### **Preliminary assessment of the water streams through the electrical conductivity in Ilha Solteira- Brazil**

J.N. Oliveira, Unesp / Civil Engineering; C.M. Brito, Unesp / Engineering Civil Since 2009 the sub-basin of stream Sem Nome, with an area of 3.47 km<sup>2</sup>, was already completely urbanized. The stream has ephemeral characteristics and its base flow is greatly reduced during dry seasons. The flow also varies during the day, increases a little after 10 am possibly due the addition of sidewalks cleaning water. The objective was to evaluate preliminarily the electrical conductivity and pH during the day. Were collected 30 surface water samples in March. Initially with an interval of 5 minutes and then 15 minutes. The analyzes were performed in the laboratory with bench pH meter Hanna pH 21. The pH ranged from 8.03 to 8.79 remained within the acceptable range according to the Resolution No. 357 of CONAMA for streams class 2. In comparison, the electrical conductivity remained within the standards suggested by the state agency CETESB only until 10 hours, increasing 68.8 µS/cm to 86.3 µS/cm. From that time there was great growth, jumping from 107.6 µS/cm to 213.5 µS/cm. Relatively high values were also found in the sub-basins of the streams of Leucena and of Cinturão Verde, which despite being adjacent, have different occupation characteristics, with less urbanized area. The average values were respectively 163.2 µS/cm and 222.5 µS/cm in August

2009. Thus it is evident that the area is impacted there is no way to know more about the source as it is not possible to infer whether the urbanization contributes or not to the high values that we found. However, apart from the impact suggested by conductivity values, field observations were made and allowed us to see that the water is usually anoxic due to low flow basis and possibly because illegal sewage connections.

#### WE107

##### **Risk survey of a chemical contamination chronicles in the space of the Marina of LA ROCHELLE: understanding of the adaptive processes of marine species**

M. Breitwieser, LIENSs UMR7266 2 rue Olympe de Gouges 17000 La Rochelle; D. Fichet, LIENSs UMR 2 rue Olympe de Gouges 17000 La Rochelle; A. Fontanaud, Port de Plaisance de La Rochelle 17000 LA Rochelle; C. Churlaud, LIENSs UMR7266 2 rue Olympe de Gouges 17000 La Rochelle; h. thomas, The evaluation of the impact of pollutants in the environment is at present one of major concerns and it with the aim of reaching to the good chemical and ecological state of the littoral circles. In this context, the objective of this work will try to better understand the natural and anthropological phenomena which affect the functioning of a Marina of La Rochelle and its close environment: pollutions (hydrocarbons, heavy metals) which impact on the specific fauna but also on the neighboring zones and on the zones of relargage of the muds of dredging. Indeed, the harbour spaces constitute zones of interesting studies in terms of obvious environmental requirements on restricted surfaces. So, the biological effects of chemical pollution in the Marina of La Rochelle were looked for by developing an approach multi-biomarkers on specific marine species of this site and to consider the environmental variability (climatic & anthropic). In this context, animals were collected on diverse intra-harbour stations in order to (1) quantify the content of the inorganic contaminants in the marine bodies, and (2) realize the follow-up of indicators of feature to identify an indicator species such as bivalves (oysters & clams) of intra-harbour pollution. These studies uses the platforms and technical site of LIENSs and will consider biochemical, physiological and/or genetic descriptors to animals. So, parameters of detoxification and enzymes of the oxidative stress were used as "alarm system" susceptible to detect a disturbance before the appearance of irreversible pathological signs. The obtained data was valued in association with the local actors (region councils) and in connection with the communications office of the Marina of La Rochelle.

##### **Changes of sessile organisms around the Fukushima Dai-ichi Nuclear Power Plant after nuclear accidents in March 2011**

T. Horiguchi, National Institute for Environ. Studies / Center for Environmental Risk Research; K. Kodama, National Institute for Environ. Studies / Center for Environmental Risk Research; T. Akatsuka, National Institute for Environ. Studies; H. Shiraiishi, National Institute for Environmental Studies / Research Center for Environmental Risk

To investigate possible adverse ecological effects caused by accidents of Fukushima Dai-ichi Nuclear Power Plants (1F) accompanied with big earthquakes and Tsunami in March 2011, we have conducted field surveys at intertidal zones since December 2011. We carried out field surveys at intertidal zones of 43 sites along the coastal line of eastern Japan from April to August 2012 and those on sessile organisms at 7 sites by 50cm x 50cm quadrat method in May/June 2013 and June 2014. The number of species of intertidal biota seemed to get smaller as the site was close to 1F in 2012. No rock shell (*Thais clavigera*) specimens were collected at 8 sites, located around 1F of Fukushima prefecture, in 2012. Because the rock shell specimens were collected at many sites in Miyagi and Iwate prefectures in 2012, where enormous Tsunami attacked, it is unlikely that small number of intertidal species and no rock shell specimens around 1F were caused only by Tsunami. Results on surveys on sessile organisms by quadrat method in 2013 showed the number of species, the number of individuals per square meters and whole wet weight of organisms per square meters were much lower at sites in the south of 1F than those in other sites, especially for Arthropoda. The densities of sessile organisms per square meters at sites in the south of 1F in 2013 were much lower than those in 1995. Cooling water, contaminated by various radionuclides and several harmful chemicals, leached from the nuclear reactors directly to the sea in March-April 2011 may have given any impacts to intertidal biota including rock shell populations and sessile organisms around 1F. Results on surveys on sessile organisms by quadrat method in 2014 will be also shown to discuss about their temporal changes.

#### WE109

##### **Impact of methylmercury exposure on marine fish ecophysiology under ocean warming and acidification**

S.d. Francisco, MARE Marine and Environmental Sciences Centre; M.S. Pimentel, J.R. Paula, Faculdade de Ciências da Universidade de Lisboa / MARE Marine and Environmental Sciences Centre; I. Rosa, University of Aveiro; V. Madeira, T. Repolho, Faculdade de Ciências da Universidade de Lisboa / MARE Marine and Environmental Sciences Centre; A.M. Marques, Portuguese Institute for the Sea and Atmosphere / Division of Aquaculture and Upgrading; A. Maulvault, IPMA, I.P. / Division of Aquaculture and Seafood Upgrading; R. Rosa, Faculdade de Ciências da Universidade de Lisboa / MARE Marine and

Climate change predictions indicate that oceans will become up to 4°C warmer and ocean pH will drop 0.4-0.5 units. These changes are expected to drive deleterious impacts on marine organism's distribution and abundance. Moreover, ocean warming and acidification are both known to exacerbate the toxicity of pollutants (e.g. mercury) to many life history stages. There are considerable evidences that mercury levels (Hg) in the environment have greatly increased in the past century. Although most Hg in the environment is inorganic, some is converted to the highly toxic methyl mercury (MeHg), which bioaccumulates in fish. Elevated MeHg concentrations is known to increase neurodevelopmental abnormalities which may trigger deleterious effects on fish behavior, performance and health. The combined impacts of ocean warming, acidification and mercury pollution on marine species are not known. In this study, we investigated, for the first time, a set of biological responses to the combined effect of methylmercury exposure, warming (+4°C) and acidification ( $\Delta\text{pH} = 0.5$  units) in meagre (*Argyrosomus regius*) juveniles, namely morphological, physiological and biochemical changes during 30 days. The potential cascading effects on the marine food webs are also discussed.

#### WE110

##### **Do warmer winter temperatures make damselfly larvae more sensitive to pesticide exposure?**

H. Arambourou, Irstea Lyon / Laboratoire détoxologie; R. Stoks, University of Leuven / Department of Biology

Global warming is expected to increase winter temperatures resulting in shortened durations of ice cover in shallow ponds at northern latitudes. Given that higher water temperatures during winter are generally associated with increase metabolic rates, this could result in a stronger depletion of energy reserves. Therefore, under global warming freshwater invertebrates may become more sensitive after winter when exposed to pesticide sprays in spring. In the present study, we tested this hypothesis in the common damselfly *Ischnura elegans* using a common-garden experiment where we investigated the combined effect of a 4°C winter temperature rise and subsequent exposure to the widely used pesticide chlorpyrifos. To assess the potential mediatory role of local thermal adaptation, we applied these treatments to larvae of replicated low- and high-latitude populations in Europe. In the larvae we measured two life-history traits (mortality and growth rate) and three biochemical markers (lipid content, acetylcholinesterase activity and phenoloxidase activity). Winter mortality was lower and growth rate higher during the simulated warmer winters (8°C) than during the simulated normal cold winters (4°C) at the high latitude. In line with a pattern of thermal adaptation, low-latitude larvae suffered a higher mortality during winter than high-latitude larvae. Subsequent chlorpyrifos exposure at 20°C induced a significant increase of mortality and decrease of growth rate, and this irrespective of the previously experienced winter temperature and the latitude of origin.

#### WE111

##### **Combined dietary effect of P and Zn on reproduction of D.magna**

C. Gao, Department of Earth and Environmental Sciences; K.A. De Schampelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; E.E. Smolders, Katholieke Universiteit Leuven / Division Soil and Water Management

Phosphorus (P) and lipids (including sterols and essential 3- and 6- polyunsaturated fatty acids (PUFAs) provide a substantial contribution to the food quality for invertebrates and are vital for somatic growth, survival, and reproductive success. Relatively little is known, however, about how chemical stress and nutritional stress (i.e. below optimal nutritional quality of diet) may interact on invertebrates. One possible interaction pathway has been documented: anthropogenic chemical stress can considerably affect P content, lipid content and/or lipid composition of algae (Gushina and Harwood, 2008; Evens, 2011; Evens et al. 2009; De Schampelaere et al. 2007; McLarnon-Riches et al. 1998) and as such cause indirect effects through the food chain. The objective of the task is to determine the combined effects between nutrition (P, lipids) and Zn toxicity on the aquatic invertebrate Daphnia, with focus on nutrition stress levels that can realistically be caused by combined nutrient and Zn stress imposed to their green algal food and furthermore to determine which specific nutritional components of nutrition (i.e. P and/or specific lipids, notably PUFAs, HUFAs and/or sterols) play an important role in interactions at the organism level (growth, reproduction). At the initial phase of the study, we are investigating the dietary effect referring to combined Zn and nutrient (P) to green algae *Pseudokirchneriella subcapitata* on the reproduction of *Daphnia magna*. Practically, Steady state of algal characteristics was achieved by constantly supplying Zn and P into the system. Six treatments were included with a factorial design of three Zn concentrations and two P supplies. Cell growth was daily monitored with frequent cell P and cell Zn analysis though the test. The algae were taken due to daily dilution and centrifuged, feeding daphnid in a reproduction test. The test was terminated until the first brood was observed. In addition, daphnia body burden of Zn and P as well as the fatty acid profile prior to and after the reproduction test were analyzed in order to get a clear view of dietary interactions on those components. Key words: Dietary toxicity, P-Zn interaction, *D. Magna*, Fatty acid composition Preference: Platform Presentation

#### WE112

##### **Effect of pathogen infection on Caenorhabditis elegans stress response to**

##### **various environmental contaminants**

Q.N. Choudhry, N. Chatterjee, University of Seoul; J. Choi, School of Environmental Engineering Graduate School of Energy and Environmental system Engineering

In most of toxicology studies, responses of organism are investigated to a single chemical exposure. However, in a real environmental condition, most of organisms are simultaneously faced to various chemical and biological stresses. We paid special attention on how pre-infection can modify the chemical induced response in an organism. To explore this phenomenon we carried out a study designed using *Caenorhabditis elegans*, which is a common model in toxicology and immunology. Worms were infected with pathogenic bacterial *Pseudomonas aurogenosa* and were subsequently challenged to chemicals for 24 hours and mortality was monitored as an end point. Various categories of chemicals, including organic compounds (nonylphenol, benzene, DEHP, PFOA, PFOS, BDE-209), heavy metals ( $\text{Cd}^{+2}$ ,  $\text{Pb}^{+3}$ ,  $\text{Cr}^{+6}$ ,  $\text{Cu}^{+2}$ ) and nanomaterials (silver nanoparticle, silica nanoparticle, titanium dioxide nanoparticle, carbon nanotubes, graphenes) were screened. Among the tested chemicals AgNP showed the rescue effect whereas cadmium, lead and nonylphenol treated worms were found more sensitive with pre-infection. Other chemicals such as benzene, DEHP, POPS, MWCNT,  $\text{TiO}_2$ ,  $\text{SiO}_2$  and graphenes did not display any changes in survival response with infection. Further study is ongoing to explore the detail mechanisms of these differential responses. Acknowledgement : This work was supported by the grant from the Korea Ministry of Environment as "Environmental Health R&D Program"(2012001370009).

##### **Comparison of two marine test species: Arcatia tonsa and Tisbe battagliai in Acute Toxicity Tests acc. to ISO 14669**

U. Noack, T. Nowakowski, DR. U. NOACK-LABORATORIEN; U. Feiler, Federal Institute of Hydrology; U. Noack, DR.U.NOACK-LABORATORIEN

Toxic pollutants enter coastal areas with water and sediment and, therefore, are often accumulated in the sediment section. As the marine meiobenthic fauna is of major ecological significance in coastal and estuarine life, determination of toxic effects to marine copepods is very important in terms of environmental hazard and risk assessment. The ISO guideline 14669 (1999) describes a method of assessing acute toxicity data with three representative benthic species *Arcatia tonsa*, *Tisbe battagliai* and *Nitocra spinipes*. Chemical substances, industrial or sewage effluents and marine or estuarine waters can be tested regarding their toxicity for these marine copepods. During the past two years, numerous acute toxicity tests with the species *Arcatia tonsa* and *Tisbe battagliai* were performed for selected environmental samples as well as for well-known reference chemicals. The results will be compared and presented with regard to differences in species sensitivity as well as test design and possible limitations of the method.

#### WE114

##### **Hepatic and renal pathology in fish from a hyper-eutrophic freshwater impoundment: species differences and seasonal variations**

C. Van Dyk, University of Johannesburg, APK campus; I. Barnhoorn, Zoology

The Roodeplaat Dam is a freshwater impoundment located in the Gauteng Province of South Africa. It is known for its hyper-eutrophic status and associated algal blooms. A previous survey has shown levels of both organic and inorganic pollutants in water samples and fish tissues as well as histological changes in selected target organs of fish. However, no cause and effect relationship was confirmed with, for example, biotoxins like microcystins, nor were seasonal differences in pathology of fish investigated considering the seasonality of algal blooms. Consequently, a study was proposed to further investigate health-related aspects of fish inhabiting this aquatic ecosystem, specifically the Sharptooth catfish *Clarias gariepinus* and the Mozambique tilapia *Oreochromis mossambicus*. Endpoints assessed included necropsy-based macroscopic screenings, target organ histopathology with special focus on the livers and kidneys, the analyses of water and fish tissue samples for selected pollutants and bio-toxins as well as possible associations between potential causative agents and the pathology identified. Both species were sampled seasonally for comparative analyses. The pathology-related results showed macroscopic liver abnormalities with associated histological changes. Multiple, large focal areas of cellular change were especially pronounced in catfish. Preliminary results also suggest that there is seasonal and species variation in the degree and/or type of hepatic and/or renal pathology observed. Associations between bio-accumulated pollutant levels and the pathology identified will be presented.

##### **Mixtures associated with cyanobacterial water blooms dominated by Microcystis species interfere with signalling of retinoids**

J. Javurek, Research Centre for Toxic Compounds in the Environment (RECETOX) / RECETOX Research Centre for Toxic Compounds in the Environment; E. Sychrova, RECETOX Research Centre for Toxic Compounds in the Environment; M. Smutna, Masaryk University Faculty of Science RECETOX; M. Bittner, Masaryk University, Fac. of Science / Faculty of Science RECETOX; J. Kohoutek, Masaryk University / Research centre for toxic compounds in the environment RECETOX; O. Adamovsky, Masaryk University, Faculty of Science, RECETOX / Research centre for toxic compounds in the environment RECETOX;

K. Novakova, Masaryk University / Faculty of Science RECETOX; S. Smetanova, Masaryk University / Research centre for toxic compounds in the environment RECETOX; K. Hilscherova, Masaryk University, Faculty of Science, RECETOX / RECETOX Research Centre for Toxic Compounds in the Environment

Freshwater ecosystems are commonly affected by multiple stressors including compounds of both anthropogenic and natural origin. Harmful water blooms are causing a number of problems such as decreased oxygen content, shading of green algae and changes in water chemistry. Cyanobacteria are also a source of toxic metabolites that can be released into water. Aquatic organisms are exposed to complex mixtures of compounds including known cyanotoxins, other cyanobacterial metabolites and anthropogenic pollutants. Their toxic potencies can be investigated through effect-based tools. Our study focused on the retinoid-like activity of the mixtures associated with water blooms. Retinoids are very important regulators of several vital processes and thus interference with their signaling can cause many adverse effects, e.g. developmental disorders. This study combines laboratory investigations with field sampling to evaluate intracellular and extracellular levels of total retinoid-like activity and retinoic acids at a set of independent sites with occurrence of water bloom dominated by widespread highly abundant species *Microcystis aeruginosa* and in its laboratory cultures. Twelve samples of biomass and surrounding water from seven localities affected by blooms were studied. Method for biomass extraction was optimized and final extracts and samples of surrounding water concentrated by solid phase extraction were assessed using *in vitro* reporter gene bioassay and chemical analyses for all-*trans*-retinoic acid (ATRA) and 9-*cis* retinoic acid (9-*cis* RA). *In vitro* bioassay with P19/A15 transgenic cell line revealed retinoid-like activity in all environmental cyanobacterial biomasses in the range 356–2838 ng of retinoic acid equivalents (REQ)/g dry mass (dm), while only three of environmental waters exhibited detectable retinoid-like activity in range 12.8–28.7 ng REQ/L. Known cyanotoxins microcystins did not contribute significantly to retinoid-like activity. REQs of environmental samples are generally higher than sum of analysed retinoic acids. Thus, total REQs cannot be explained by the presence of ATRA and 9-*cis* RA alone, which implicates there are more compounds acting through retinoic acid receptor-mediated mode of action. Impact of retinoid-like cyanobacterial metabolites could be of importance namely in smaller water bodies with dense water blooms and low dilution. The research was supported by the Czech National Science Foundation grant No. P503/12/0553.

#### WE116

##### **Influence of temperature on the single and combined toxicity of relevant polycyclic aromatic hydrocarbons to planktonic microalgae**

L.R. Vieira, CIIMAR - University of Porto / Laboratory of Ecotoxicology Group of Ecotoxicology Stress Ecology and Environmental Health; F. Morgado, CESAM Universidade de Aveiro / Biology; L. Guilhermino, CIIMAR University of Porto

In the present context of global warming, more knowledge on the combined effects induced by temperature changes and mixtures of environmental contaminants is urgently needed. Therefore, the main objective of this study was to investigate the effects of temperature increase on the toxicity of two polycyclic aromatic hydrocarbons (PAHs), namely benzo(a)anthracene (BA) and fluorene (FL), alone and in mixture, to the marine planktonic algae *Tetraselmis chuii*. *T. chuii* cultures were exposed for 96h to different concentrations of the PAHs, individually and in binary mixtures, at both 20 and 25 °C. The effect criterion was the inhibition of culture growth. The increase of temperature by 5 °C significantly increased the toxicity of both tested PAHs. Toxicological interactions among the stressors were also found, highlighting the need of more research on the topic.

#### WE117

##### **Filtration rates of the native and non-native freshwater fish and potential control on cyanobacteria species: experimental approach**

I.R. Rodrigues; D.M. Failace, D.M. Marques, Universidade Federal do Rio Grande do Sul

The objective of this study was to investigate experimentally measured control of cyanobacteria by using filter fishes. Cosms experiments were conducted to evaluate the consumption rates of *Microcystis aeruginosa* and *Cylindrospermopsis raciborskii* by *Oreochromis* sp. and *Geophagus brasiliensis*. Were determined treatments in triplicate consisting of fish of two size classes (Treatment 1: fish 5-10 cm; Treatment 2: fish 10-15 cm); three cyanobacterial concentrations (10µg/L, 20µg/L and 40µg/L) and controls. In order to show differences between treatments analysis of variance (*two-way* ANOVA) was performed. Morphological analysis in the gills of specimens used in the experiments were carried out using scanning electron microscopy (SEM) to verify the existence of structures related to filtration efficiency in these fishes. As a result, the experiment with *Oreochromis* sp. to ingestion/filtration of *M. aeruginosa* at all concentrations the reduction in concentration of cyanobacteria was significant ( $p < 0.05$ ), while the test organism was the T1 decrease in the concentrations of cyanobacteria and the T2 test organism was increasing concentrations of cyanobacteria over time. In the experiment using *Oreochromis* sp. front ingestion/filtration of *C. raciborskii*, was observed significant differences ( $p < 0.05$ ), except for the test organisms in the T1 concentration 40µg/L. In the experiment with *G. brasiliensis* front ingestion/filtration of *M. aeruginosa* did not were observed significant differences in concentrations 20µg/L and 40µg/L. In concentration 10µg/L was observed significant differences ( $p < 0.05$ ). However in an experiment using *G. brasiliensis*

front ingestion/filtration of *C. raciborskii* in concentrations 10µg/L and 20µg/L were observed significant reduction ( $p < 0.05$ ) the concentration of cyanobacteria, while the concentration 40µg/L did not was observed significant differences. Results of morphological analysis revealed the existence of gill microspine, both in *Oreochromis* sp. as for *G. brasiliensis* validating the possibility of *G. brasiliensis* can be used as natural control of cyanobacteria. These results are important for knowledge management and restoration of eutrophic aquatic ecosystems based on species interactions.

#### WE118

##### **Can elevated pesticide concentrations in sediments indicate past acute pollution events?**

V.J. Pettigrove, The University of Melbourne / Zoology; S. Mohr, Umweltbundesamt / IV; L. Reiber, Helmholtz Center for Environmental Research; S. Marshall; B. Gagliardi, The University of Melbourne / Zoology; S. Meinecke, Umweltbundesamt

Pesticides are usually measured in the surface waters of streams but rarely in sediments. However, several studies have found high concentrations of many pesticides in sediments compared to overlying waters. Some of these pesticides such as organochlorines, organophosphates and synthetic pyrethroids are hydrophobic and are expected to bind to sediments; however, recent surveys of some streams in Victoria, Australia have detected hydrophilic pesticides such as the herbicide simazine and the fungicides myclobutanil and pyrimethanil at concentrations from 100 to 1,000 times higher in sediments than in overlying waters. Sites where this occurred were typically located downstream of intensive horticulture operations with a history of heavy pesticide use. This suggests that the elevated concentrations in sediment may indicate recent acute pollution events, and that sediments may act as passive samplers for hydrophilic pesticides more generally. We tested this hypothesis by conducting an experiment in two 100 m long artificial streams where we spiked the surface waters with high concentrations of the herbicides simazine (30 µg/L) and atrazine (30 µg/L), the neonicotoid insecticide imidacloprid (50 µg/L), and the fungicides myclobutanil (100 µg/L) and pyrimethanil (100 µg/L). The sediments consisted mostly of fine sands with the exception of four 2m long blocks in each stream that contained fine sediments. The carbon content was 0.9% in half of these blocks and 0.1% in the other half. The surface water was replaced by clean water 12 hours after spiking to simulate a spray event, and the pesticide concentrations were then monitored over the next 28 days in surface waters and sediments. Pesticide concentrations remained low in the surface waters over this period, but remained elevated in sediments for several weeks following the initial spiking. This experiment confirms that sediments can act as effective passive samplers for some pesticides and could serve as potential indicators of recent acute pollution events.

#### WE119

##### **The Guadiana River Estuary salinization, an opportunity for traditional sea salt production recovery**

N. Sainz, Universidad de Cadiz and Universidade do Algarve; T. Boski, University of Algarve / CIMA

This study evaluates how changes in the volume of freshwater input due to dams' construction affect water salinity downstream and how this can induce changes in sea salt production and socio-economy in the Guadiana estuary, which is a natural southern border between Spain and Portugal. Fluvial discharge of Guadiana has changed over the past few decades, since river flow has been substantially reduced by the construction of tens of dams in the river watershed; the largest and the most recent being the Alqueva dam (2002). Mean monthly river flow used to vary markedly on a seasonal and yearly basis, but a sharp increase in salinity in the river mouth has been reported. In 1959, the tidal channel of Leziria of Castro Marim Municipality (Portugal) was supplying water to salt works with an average salinity of approximately 21.5‰, and after the closure of the last dam the same channel can reach a salinity of 30‰ during the salt production period. The observed salinization in the Guadiana estuary applied to a recovery of the abandoned traditional salt production in the area would cause an increase of 46,3% in the salt produced at the same land surface, and assuming the same evaporation rate for both levels of initial salinity. Although researchers have linked damming and changes in freshwater input with ecological changes detrimental to the estuarine environmental quality, the creation of employment on the Portuguese Guadiana River basin could benefit from the salinization of the lower estuary with the recovery of abandoned traditional salt works. Active salt works apart from creating habitats favouring high bird diversity and cultural heritage are one of the few activities allowed currently in the lower estuary, protected by several overlapping nature protection legal acts and international conventions. The economic benefits for this depressed area would depend on the diversification of salt production, such as the production of coarse salt or "fleur de sel" which different market values, as well as the capacity to commercialize new products. The identification of socio-economic benefits linked to observed environmental changes shows that the empowerment of traditional activities in particular areas may reverse the trend of the abandonment of environmentally-friendly practices, recovering semi-natural habitats and diversifying an economy based on irrigation fields and tourism, yielding a sustainable territorial development.

### Retinoid-like compounds produced by phytoplankton

J. Priebojová, Masaryk University, Faculty of Science, RECETOX; E. Sychrova, RECETOX Research Centre for Toxic Compounds in the Environment; M. Smutna, K. Novakova, Masaryk University / Faculty of Science RECETOX; K. Hilscherova, Masaryk University, Faculty of Science, RECETOX / RECETOX Research Centre for Toxic Compounds in the Environment

One of the less investigated modes of action of endocrine disrupting compounds is the interference with signalling of retinoids (known as dietary hormones). Retinoids comprise a family of polyisoprenoid lipids which include vitamin A and its natural and synthetic analogues. Retinoids play an important role in vertebrate development, they regulate multiple vital processes, e.g. cell proliferation, differentiation and morphogenesis. Available studies document that signalling of retinoids can be affected by some environmental pollutants. The aim of our work was to evaluate ability of phytoplankton to produce retinoid-like compounds, which could be released into the environment. The study included various cyanobacteria and algae representing several different orders. We tested *in vitro* potential of mixtures of bioactive compounds from laboratory-cultured phytoplankton species to induce responses mediated through retinoid acid receptor (RAR) using murine embryonic carcinoma cell line luciferase reporter, which contains reporter luciferase gene under the control of retinoic acid-responsive element. Extraction process was optimized for maximal yield of bioactive compounds from studied species. We found activation of retinoid receptor after exposure to intracellular and extracellular samples from different species including both cyanobacteria and algae. Variability of production of retinoid-like compounds including also the influence of light conditions was characterized in more detail for selected species, which are frequently occurring at high abundances in the fresh water environments. The detailed investigations focused on one coccal (*Microcystis aeruginosa*) and one filamentous cyanobacteria (*Aphanizomenon gracile*) and an algae (*Desmodesmus quadricauda*). The extracts of the three selected species showed mean retinoid-like activity in the range of 705 - 3098 ng ATRA/g dry weight. In case of exudates, mean retinoid-like activity was in range of 96 - 779 ng ATRA/L for the cyanobacteria, while the exudates of the alga *Desmodesmus quadricauda* showed no detectable activity. Our study underlines the ability of various species of both of cyanobacteria and algae to produce retinoid-like compounds. They could be most important and relevant in aquatic ecosystems with high abundance of retinoid-producing species, e.g. in case of massive water blooms especially in shallow water bodies. The research was supported by the Czech National Science Foundation grant No. P503/12/0553.

## Soil Ecology and Ecotoxicology: Pillars Supporting the Conservation and Protection of Soil Biodiversity and Ecosystem Services during the International Year of Soils (P)

## WE126

**Pesticide risk assessment for soil living organisms: the present and the future**  
P. Sousa, IMARCA / Department of Life Sciences University of Coimbra; M. Arena, EFSA - European Food Safety Authority / Pesticides; D. Auteri, Auteri / Pesticides Unit; A. Ippolito, EFSA - European Food Safety Authority / Institute for Environment and Sustainability IES; R. Sharp, EFSA - European Food Safety Authority / Pesticides Unit; F. Streissl, EFSA / Pesticides Unit; C. Szentes, Pesticides Unit

In view of the revision of the current terrestrial guidance document (European Commission, 2002), EFSA has launched in 2009 a public consultation to collect inputs on issues and gaps in the current risk assessment for soil organisms. According to the comments received during the consultation and the mandate as received by the Panel on Plant Protection Products and their Residues, one of the main goals in the revision of the guidance will be the development of specific protection goals for soil organisms. Examples of ecosystem services driven by soil invertebrates in the agricultural landscape, according to Millennium Ecosystem Assessment (2005), might be: soil formation and retention, nutrient cycling, reduction of soil erosion, disease and pest control, as well as soil remediation and waste treatment driven mainly by soil microorganisms. The current risk assessment of pesticides for soil organisms uses, at the first tiers, laboratory toxicity studies on earthworms. Based on the physical-chemical properties of the pesticides, such as the log  $P_{ow}$ , and environmental properties, additional toxicity studies with soil macro-invertebrates other than earthworms may also be required. Due to their easy amenability for toxicity test, earthworms have been considered as the most appropriate invertebrates to be used for risk assessment. However, Frampton et al. (2006) demonstrated that the standard test earthworm *Eisenia* spp was the least sensitive species to insecticides based on laboratory studies investigating the acute effects to pesticides (i.e.  $LC_{50}$  values) on a range of soil invertebrates. These results were also confirmed by Daam et al (2011) who also reported Arachnids and isopods as being more sensitive to insecticides, and nematodes to fungicides, in comparison to *E. fetida*. Considering the relatively high  $LC_{50}$  values reported for *E. fetida* and its absence from agricultural environments, Pelosi et al. (2013) also recommended the use of *A. caliginosa* as model species. Whilst these comparisons have mainly focused on the acute effects, it also questioned the appropriateness of *Eisenia* spp.

as test species for chronic assessments. In addition, for a more robust risk assessment, further considerations and recommendations are needed that should take into account not only sensitivity issues, but also the other traits related to species vulnerability.

## WE127

### Which is the relevant soil depth to assess the risk for soil organisms exposed to PPP?

S.E. Egerer, Umweltbundesamt; P. Kotschik, D. Felsmann, UBA Umweltbundesamt; W. Koenig, Federal Environment Agency (UBA); S. Pieper, German Federal Environment Agency (UBA) / Plant Protection Products

Recent concepts regarding the environmental risk assessment (ERA) for soil organisms exposed to plant protection products (PPP) suggest that relevant soil depths to calculate predicted environmental concentrations (PEC) should relate to so called ecological relevant soil depths typical for the vertical home range of different soil organism groups (e.g. EFSA Journal 2010;8(10):1820). The hypothesis that the toxic effects of active substances (a.s.) relate to the typical vertical living range of organisms and therefore are captured by a mean PEC for the entire horizon has not been substantiated up to now. To support further discussion, several data on vertical distribution of animals and a.s. in the soil profile are presented here. *Toschki et al.* (2014), for example, report that soil organisms living deeper in soil are affected by topically applied a.s. which predominantly remained in the top centimeter during the entire experiment. Hence, linking effects and exposure through the soil profile will not be simply straightforward. Substances applied on soils will always display highest concentrations immediately after application and in the upper centimeter of the soil. In our opinion, ERA for soil organisms exposed to PPP should therefore consider in a first step the upper first soil centimeter as the relevant depth to describe a realistic worst case independently from the organisms' home range. The initial conditions soil organisms are exposed to in the field are a pronounced vertical stratification of the a.s. concentrations and not a mean concentration through different depths. It is postulated that, if the concentration in the upper soil layer is high enough to elicit effects, a relevant share of the soil biocenosis will be exposed to it either because they live principally in the upper centimeters or because they move in the soil profile. In a refinement step, numerical models are considered suitable tools to estimate the distribution of a.s. in soil profiles over relevant time frames depending on their fate properties. The soil layer containing the largest proportion of a.s. after a given time might indicate the relevant depth to calculate the PEC. Such refinements might be suitable to address questions of recovery or recolonisation of soil organisms after initial effects due to PPP use. *Toschki et al., 2014: Evaluation of the risk for soil organisms under real life condition, presentation 350, SETAC Europe 24th Annual Meeting, Basel, 15.05.2014*

## WE128

### Is the risk for soil arthropods covered under the current ERA scheme?

D. Ruf, Agroscope Changins-Wädenswil; E. Kohlschmid, O. Daniel, Agroscope / Institute for Plant Production Sciences IPS

Testing of effects on earthworms and terrestrial non-target arthropods (leaf dwelling species) is an integral part of the ecotoxicological risk assessment for the authorisation of plant protection products. In contrast, testing of effects on soil arthropods is only required if the risk assessment of foliar applications raises concerns regarding non-target arthropods or the product is applied directly on or into the soil (Commission regulation (EU) 283/2013). It has been shown that soil arthropods are substantially more sensitive to several active ingredients (insecticides, fungicides and herbicides) than earthworms, indicating that the earthworm based risk assessment for soil organisms might underestimate the risk for soil arthropods. Thus, the question arises whether the risk assessment for non-target arthropods would trigger the testing of effects on soil arthropods in such cases. To answer this question a survey of information available in the Swiss ecotoxicological database, EFSA conclusions on pesticides and the open literature is conducted. The results will be presented and further needs for risk evaluation on soil arthropods are discussed.

### An ecosystem services framework for revealing trade-offs in crop production

A. Holt, The University of Sheffield / Animal and Plant Sciences; L. Maltby, The University of Sheffield / Dpt of Animal Plant Sciences; A. Alix, Dow Agrosciences / Risk Management; A. Thompson, Dow Agrosciences

@font-face font-family: "Arial"; @font-face font-family: "MS ?"; @font-face font-family: "Cambria"; p.MsoNormal, li.MsoNormal, div.MsoNormal margin: 0cm 0cm 10pt; line-height: 115%; font-size: 11pt; font-family: "Times New Roman"; div.Section1 page: Section1; Policy makers and industry are increasingly recognising the need for an ecosystem approach to achieve the sustainable intensification of agriculture. Agroecosystems need to be managed for multiple, often competing, human benefits (i.e. ecosystem services), namely: food production, the ecosystem functions that support food production (e.g. nutrient cycling, prevention of soil erosion and pollination), ecosystem attributes that underpin recreational benefits, enhance flood alleviation and provide cultural services. A conceptual framework, developed to aid decisions about managing the multiple functions of agroecosystems is demonstrated. The framework is tested using a case study of wheat production in the UK. We use two scenarios to explore

the potential consequences of the EU decision to restrict neonicotinoid use and the review of authorisations under EU pesticide regulations on winter wheat production. Impacts of the most commonly used pesticides for winter wheat and associated break crops were evaluated by assessing: hazard, need for risk mitigation, and risk mitigation measures required. The consequent direct impacts on ecosystem services were estimated. We found that restricting pesticide use can protect the production of multiple ecosystem services, however, tighter pesticide regulations and risk assessments may reduce yields significantly, threatening the viability of farm businesses, food security in the UK, EU and potentially globally. Hard choices need to be made about which ecosystem services we enhance where, for the benefits we consider most critical.

#### WE130

##### **Getting Rid of Formalin: Using AITC and Mustard Powder Preparations for Earthworm Extraction in Combination with Handsorting**

T. Vollmer, Eurofins Agrosience Services EcoChem GmbH / Field Ecotoxicology; O. Klein; S. Knaebe, EAS EcoChem GmbH / Ecotox Field Currently, an ad-hoc group led by the German Federal Environmental Agency is working on transforming the existing ISO guideline for earthworm field testing (ISO 11268-3: Soil quality – Effects of pollutants on earthworms) into an OECD guideline. This transformation process provides the possibility to generally adapt the method to the latest developments and requirements. One of the topics under discussion is the choice of the chemical for extracting deep-burrowing earthworm species from soil, as the present standard extraction fluid formalin is known to be hazardous to humans and to the environment and should therefore be replaced by an alternative extracting agent with more favourable properties. Mustard powder (ground seeds of *Sinapis alba* L.) and AITC (Allyl-Isothiocyanate) have already been proposed by several authors (e.g. Zaborski (2003) and Bartlett et al. (2006)) as alternative expellants with mixed results when applied directly to the soil surface. We present results from field experiments conducted in 2010-2014. The overall aim was to compare the efficiency of aqueous solutions of mustard powder of different preparations and of AITC in extracting earthworms from the soil below hand-sorting holes to that of a formalin solution as described in the current guideline. Earthworm extractions were performed at 8 different sites, all located in southern Germany and differing with respect to soil characteristics (pH, soil texture), land use (arable, grassland) and earthworm populations. Each site was sampled one to three times during periods of high earthworm activity. At each site and sampling occasion, 4 to 6 replicates (holes of 0.25 m<sup>2</sup>, 0.2 m deep) per expellant were sampled. Our results indicate that AITC and mustard powder are suitable replacements of formalin for the extraction of deep-burrowing earthworms from below hand-sorting holes. Pros and cons of the expellants will be discussed with regard to extraction efficiency, practicability of use in the field, and user- and environmental safety considerations. **References** Bartlett, M. D., Harris, J. A., James, I. T. & Ritz, K. (2006): Inefficiency of mustard extraction technique for assessing size and structure of earthworm communities in UK pasture, *Soil Biol. and Biochem.* **38**(9), 2990 – 2992. Zaborski, E. R. (2003): Allyl isothiocyanate: an alternative chemical expellant for sampling earthworms, *App. Soil Ecol.* **22**(1), 87 – 95.

#### WE131

##### **Assessing the potential for intrinsic recovery in a Collembola two-generation study - possible implementation in a tiered soil risk assessment approach for plant protection products**

G. Ernst, Bayer CropScience AG / Ecotoxicology; P. Kabouw, BASF SE; M. Barth, BioChemagrar GmbH; U. Frommholz, Bayer CropScience; S. Royer, BASF SE, Global Ecotoxicology, Crop protection; S. Friedrich, BioChem agrar GmbH A Collembola two-generation study was developed in order to assess the potential for intrinsic recovery within an intermediate tiered collembola risk assessment approach for plant protection products. Juvenile individuals of *Folsomia candida* hatched under impact of a test substance in a modified OECD 232 bioassay were introduced into a second consecutive bioassay containing the aged test substance in soil. This test system determines whether a population which was initially impacted by a substance in a 1<sup>st</sup> bioassay shows normal reproduction and survival in a 2<sup>nd</sup> bioassay after aging of the test substance in soil. Case studies indicated that the collembola two-generation study is a sensitive test system. After an initial effect on *F. candida* in the 1<sup>st</sup> bioassay it depends on the properties of the substance whether the toxicity is reduced in the 2<sup>nd</sup> bioassay. In case persistent substances were applied the toxicity did not decrease remarkably in the 2<sup>nd</sup> bioassay. Contrastingly, fast degrading or dissipating substances were shown being of reduced toxicity in the 2<sup>nd</sup> bioassay revealing potential for intrinsic recovery of Collembola. Thus, the collembola two-generation study is able to differentiate between substances showing a potential long-term effect and substances causing only short term effects. Comparing the results of the two-generation studies with effect data from semi-field and field studies indicates a high degree of conservatism using the collembola two-generation study as an intermediate tiered test system. This approach represents a valuable and efficient tool for the soil risk assessment providing an intermediate tiered refinement option for highly conservative tier 1 collembola risk assessment.

#### WE132

##### **Natural variation of Collembola abundances on agricultural sites**

P. Kabouw, BASF SE; J. Lueckmann, M. Cartay, M. Faupel, Rifcon GmbH Collembola field studies are frequently conducted as part of the risk assessment of plant protection products (PPPs). Currently no guideline and exact assessment criteria are available, making meaningful evaluation of these studies difficult. Collembola communities are typically highly variable in their abundance and composition; therefore interpreting whether or not, after application of a PPP, a risk is indicated is challenging. In order to support evaluation of potential PPP effects on Collembola communities, we present the results of the control treatments from five field trials conducted with PPPs. The variations of abundances (based on the relative standard deviation of mean abundance) at two different spatial levels were determined at the species level. Results show variations up to a 3.5-fold of mean abundance (for *Isotomurus palustris*) with most species varying by a factor of 1.5 - 2.5. *Mesaphorura critica* (found at only 1 of 5 sites) showed the least variation, i.e. a 1.4-fold of its mean abundance. Species specific differences were observed for both low and highly abundant taxa. These differences should be considered when interpreting Collembola field data. Overall, *Mesaphorura krausbaueri* appeared to be an appropriate representative species for field studies in the context of PPP registration as it was found at all test sites in relatively high abundances and showed relatively low variability in comparison to other species.

#### WE133

##### **Field monitoring of soil mesofauna in conventional (chlorpyrifos-treated) and organic Cider-Apple Orchards in Herefordshire UK: Differences in Collembolans, Mites and Enchytraeids**

J. Leopold, IBACON GmbH / Terrestrial Ecotoxicology; S. Norman, RidgewayEco; N.N. Poletika, Dow Agro Sciences LLC / Field Exposure and Effects Department

The influence of chlorpyrifos on diversity and abundance of soil mesofauna (Collembola, mites, enchytraeids) was monitored for two years. 3 conventionally-managed (chlorpyrifos-treated) cider-apple orchards were chosen as trial sites. 3 organically-managed cider-apple orchards and field margins at the edges of the conventional orchards served as 'references'. These references are intended for general comparison with the numbers of sampled organisms from within the conventionally-managed orchards. All trial sites were located in Herefordshire, a major cider-apple growing area in England. Chlorpyrifos was applied bi-annually, for the control of apple blossom weevil and sawfly (both impact apple yield). 12 soil organism samplings were carried out between April 2013 and April 2015. In the conventional orchards all trees were arranged in rows with defined distances within and between the tree rows, separated by 'tramlines'. These tramlines were intensively driven-on by tractors during plant protection and maintenance measures. In organic orchards the employment of large machines was less intensive and clear tramlines were missing. Moreover, tree density was lower and 2 orchards were extensively grazed. 2 types of sampling areas were established in each orchard: tramline and tree row. Additionally, only in the conventional orchards, field margins, which were located near hedges that served as borderlines were used as a third type. Heat extraction of soil cores in a Mac Fayden apparatus and funnel pitfall traps were used to sample eudaphic and (hemi)edaphic collembolans and soil mites. 6 cores (depth 5 cm, diameter 5 cm) were taken from each sampling area at each sampling occasion. 12 pitfall traps were installed in-crop in each orchard. The traps were placed in 4 lines of 3 traps each. 2 lines were placed within the tree rows and 2 lines were centrally arranged in the space between the rows. For the off-crop (in-field) grassed margins 6 pitfall traps were placed in a line. All traps were opened for 3 days. A wet extraction method was used to collect enchytraeids from soil cores. At each sampling occasion 5 cores (depth 20 cm, diameter 5 cm) were taken from each sampling area. Differences in soil organism density and distribution between conventional (chlorpyrifos-treated) and organic cider-apple orchards will be presented. Additionally, the effect of unfavourable weather conditions and the role of physical differences in cultivation practices will be discussed.

#### WE134

##### **Towards an understanding of the sensitivity of pesticide degradation to losses of soil microbial diversity**

J. Princiville, Geography and Environmental Science; P. Thomas, CEHTRA SAS / Ecotoxicology and Risk Assessment; S.J. Marshall, Syngenta Ltd / Product Safety; L. Shaw, University of Reading; L.H. Hand, Syngenta Limited / Product Metabolism; I. Bramke, Syngenta Ltd / Product Safety Soil microbial communities are highly diverse and implicated in delivering many ecosystem services including the *degradation of pesticides*. However, evidence is increasing that field soils, once sampled, processed and incubated according to OECD guidelines are less microbially diverse than field soils *in situ*. In addition, field soils undergo regular perturbation and recovery, which may impact microbial diversity and pesticide biodegradation. For many pesticides significant lab-to-field and soil-to-soil variability of degradation rates (DT<sub>50</sub>) has been reported, but the relationship between microbial diversity and pesticide biodegradation kinetics has not yet been examined. This study explores the sensitivity of pesticide biodegradation to microbial diversity erosion and aims to better understand the causes of DT<sub>50</sub> variability. Soil mesocosm series encompassing a microbial diversity gradient were created using a dilution to extinction approach. Mesocosms of fresh and sterile soil were included as controls. Following a five month equilibration, measurements of microbial biomass (SIR) showed that the

mesocosms had reached similar levels of bioactivity. OECD307-compliant aerobic soil degradation studies of four model pesticides (2,4-D, Terbutylazine, Azoxystrobin, Bicyclopyrone) were conducted using these equilibrated soils. Analysis of compound degradation rates revealed pesticide-specific sensitivity to microbial erosion as well as clear differences in the patterns of response. The microbial 2,4-D degradation function was robust up to  $10^{-6}$  dilution, but was disrupted in highly impoverished systems. Conversely, Azoxystrobin half-life was much prolonged (>417 days) in all diluted mesocosms compared to the 'fresh control' DT<sub>50</sub> of 77 days, indicating a high dependency on microbial diversity. Degradation of Terbutylazine did not follow the trend (more erosion = longer half-life/lower rate) observed for 2,4-D and Azoxystrobin. Data so far indicates that this test system is suitable for studying the impact of microbial diversity erosion on pesticide biodegradation function. Our findings suggest that structurally different chemicals respond differently to microbial diversity erosion. Differences in microbial diversity may therefore explain, at least in part, soil-to-soil variation in the field and changes in microbial diversity occurring during processing of soils for lab studies may therefore explain some of the lab-to-field variation frequently observed.

#### WE135

##### **Diplopods as soil bioindicators: morphological alterations in the midgut cells of *Rhinocricus padbergi* exposed to a metallic-insecticide**

R.B. Souza, Sao Paulo State University - UNESP / Biology; C.M. Sousa, São Paulo State University - UNESP / Biology; J.B. Fernandes, Universidade Federal de São Carlos / Química; R.M. Carlos, UFSCar; O.C. Bueno, Universidade Estadual Paulista / Centro de Estudos de Insetos Sociais; C. Fontanetti, Sao Paulo State University - UNESP / Biology

keywords: histopathology; histology; millipedes; soil ecotoxicology Diplopods play an important role in the dynamic of soils, where they occupy the trophic level of decomposers, since they promote its aeration and enrichment. Due to their habits, some researchers have discussed their use as bioindicators in soil ecotoxicological studies, using midgut histopathology as a biomarker. This technique enables diagnosing cellular and subcellular symptoms resulting from intoxication, as well as symptoms of cellular death. It can also reveal reactions in response to chronic and sublethal exposures in cells and tissues. Nowadays, the indiscriminate use of pesticides in soil is one of the main environmental problems. The most efficient active ingredient to ant control is sulfluramid, but it was prohibited by the Stockholm Convention due to its high toxicity. As an alternative, researchers have developed a metallic-insecticide, whose formula consists in a natural product complexed with an inorganic metal. Thus, the aim of this study was to analyze morphological alterations in the midgut cells of diplopod *Rhinocricus padbergi* induced by the metallic-insecticide  $Mg_6[Mg(5\text{-metil-phen})(hesperitin)(H_2O)_2](CH_3COO)_6$ . Three treatments were performed: control, using soil from the local where the animals were collected, and two treatments containing metallic-insecticide at the concentrations of 0.5 mg/mL e 1.0 mg/mL. Nine animals were placed in each treatment. After 21 days, 3 animals from each treatment were dissected and the midgut was prepared for histological routine; slides were stained with hematoxilin-eosin. The histopathological alterations were analyzed semi-quantitatively for each diplopod. The data obtained in histopathological evaluation were compared to the results obtained for the individuals exposed to the control soil sample with the Kruskal Wallis test and  $p < 0.05$ . Increase in epithelial turnover, release of secretion vesicles and presence of granules in hepatic cells were observed in animals exposed at both concentrations. However, none of these alterations were statistically significant. Therefore, the metallic-insecticide was not toxic to *R. padbergi*. Financial Support: FAPESP (2012/12019-5)

#### WE136

##### **Ecotoxicological assessment of the effects of agrochemicals on non-target organisms**

S. Curieses; m. saenz, Universidad Nacional de Lujan CONICET; J. Alberdi, UNLU; W.D. Di Marzio, Universidad Nacional de Lujan-CONICET Increasing world use of synthetic herbicides and insecticides to sustain high – yielding crop varieties may affect non target organisms. The pampasic region of Argentina is severely affected by agricultural contamination due to an increase of agrochemical use in transgenic soybean crops. In the last year the extension of the soybean crops in the region has reach to about fourteen million hectares. The herbicide glyphosate and the organophosphorus insecticide chlorpyrifos are frequently used not only in Argentine fields but also worldwide. It is recommended to evaluate the potential environmental risk of agrochemical by using a battery of biomarkers and organisms. The aim of present study was to evaluate the usefulness of a series of endpoints for assessing adverse effects of the extensive use of agrochemicals. The soils were sprayed with commercial chlorpyrifos or glyphosate at manufacturers' recommended rate. Also, soils of extensive fields were analyzed. Water elutions of contaminated soils were performing for determinate agrochemical mobility in the environment. Biomass growth, level of lipid peroxidation, antioxidative stress enzymes (catalase and peroxidase) in *Vicia faba* roots, and genotoxicity in coelomocytes of *Eisenia fetida* were assayed for aqueous elutions evaluation. Root elongation, seed germination in *Lactuca sativa* and genotoxicity in coelomocytes of *Eisenia fetida* were performed for soils evaluation. The results show both agrochemicals exert toxic effects in assayed species. The

agrochemicals induce phytotoxicity in *Lactuca sativa* seeds, stimulate activity enzymatic in *Vicia faba* roots, and increase levels of DNA damage in coelomocytes exposed to *ex situ* or *in vivo* conditions. In the present work a battery of bioassays and biomarkers has been assessed on soils treated with glyphosate and chlorpyrifos. This study show dangerous effects in several organisms of glyphosate and chlorpyrifos formulations when applied at the recommended concentrations. The results indicate intensive use of both agrochemicals in crops could represent a risk for soil biota.

#### WE137

##### **Assessing the ecotoxicity of gold mine tailings utilizing earthworm and microbial assays**

M. Maboeta, C. Van Collier-Myburg, North-West University Problems associated with mining are the disposal of wastes on tailings disposal facilities (TDF) resulting in possible soil contamination. Earthworm and microbial essays can be utilized to assess the ecotoxicity of contaminants. The aim of this study was to determine the ecotoxicity of gold mine tailings by using earthworm (*Eisenia andrei*) bioassays, neutral red retention time analysis (NRRT) and enzymatic analyses. Endpoints included changes in biomass, reproduction, mortality, lysosomal membrane stability (NRRT), tissue metal concentrations, dehydrogenase activity,  $\beta$ -glucosidase, urease, acidic phosphatase and alkaline phosphatase analyses. Results indicated high concentrations of Ni in the material as well as bioaccumulation of lead and arsenic in the earthworm body tissue after exposure. Enzymatic activity was higher in the revegetated tailings than in the unrehabilitated tailings. It has been illustrated that TDFs and surrounding areas have an acidic pH which affects earthworms and metal bioavailability. Soil enzymatic activities in reference soils were significantly higher compared to those of TDFs making a sensitive indicator of metal pollution in mining areas. Growth, reproduction and lysosomal membrane stability of earthworms has also been shown to be sensitive endpoints to assess the ecotoxic effects of gold TDFs.

#### WE138

##### **Application of a single species and microbial test method suite for the assessment of copper substances in soil**

S. Kvas, Environment Canada / Biological Methods; E. Ritchie, C. Fraser, H. Lemieux, A. Crossman, M. Lazarus, R. Subasinghe, Environment Canada / Biological Assessment and Standardization Section; J. Princz, Environment Canada / Biological Assessment and Standardization Section; L. Beaudette, Environment Canada / Ecotoxicology and Wildlife Health Division; R.P. Scroggins, Environment Canada / Biological Methods Flora, fauna and microorganisms are important components of a healthy soil. As such, a multi-testing approach involving each component is required to best estimate the risk associated with contaminants in soil. To evaluate the impact of two copper substances (copper oxide (CuO) and copper sulfate (CuSO<sub>4</sub>)) in a sandy loam field-collected soil, a series of single species and microbial tests were applied. Effects on plant (red clover and northern wheatgrass) growth and invertebrate (*Eisenia andrei* and *Folsomia candida*) survival and reproduction were evaluated. A comprehensive suite of microbial tests were also applied including biomass assessment (heterotrophic plate count and fumigation extraction), activity (organic matter decomposition, nitrification, and respiration) and community structure (enzyme assays, community level physiological profiling, and DNA sequencing) followed by data integration of each microbial test. To ascertain the effect of copper in each test, total and ionic (e.g., using an ion selective electrode) soil copper were measured. This comparison may be useful in future copper substance toxicity research where only the ionic portion will be measured.

#### WE139

##### **Estimation of soil health index using metal-remediated soil**

S. Kim; J. Kwak; S. Nam; R. Cui, Y. Chae, J. Moon, Konkuk University; S. Jeong, Kunsan National University / Dept of Environmental Engineering; Y. An, Konkuk University / Department of Environmental Science Soil health index (SHI) was proposed to evaluate the soil health before and after remediation. SHI was based on the standard process including 1) determination of assessment factor (AF), 2) indicator classification, 3) indicator ranking and weighting, 4) indicator scoring, and 5) calculation of soil health index (SHI). The soil function related AFs were determined as soil productivity (SP), soil stability (SS), biodiversity (Bd), and risk (Ri). Soil productivity have assessment indicators including physical stability (aggregate stability, bulk density, texture), water relations (infiltration, water holding capacity), nutrient cycling (cation exchange capacity, organic matter, total nitrogen, pH, total phosphorus, enzyme activity), and crop productivity (plant growth, photosynthetic capacity). Soil stability includes the physical (aggregate stability, bulk density, texture, water holding capacity), chemical (cation exchange capacity, organic matter, pH), and biological stability (earthworm activity, total glomalin related soil protein, enzyme activity). The indicators for biodiversity evaluation were chosen as earthworm, microbial biomass C, nematode, plant, soil algae, and springtail diversities, and the soil contamination concern standard and bioaccumulation were assessed for human and ecological risk evaluation. Indicator ranking and weighting of each AF was determined using principal component analysis (PCA) and factor analysis (FA) method. The total data set of indicators in each AF was scored using standard scoring functions (more-is-better, less-is-better, and optimum), and soil health indexes of SS, Bd, Ri

calculated by integration of each weighted indicator score. Final SHI was determined using sum of each weighted SHI. *This subject is supported by Korea Ministry of Environment as the GAIA project (2014000560001).*

#### WE140

##### **Evaluation of algal inoculation method for assessing soil algal toxicity**

S. Nam; Y. An, Konkuk University / Department of Environmental Science

To expand biological diversity of terrestrial toxicity data, it is needed to focus on soil algae which act as a food source for many microfauna and mesofauna.

However, there were no international guidelines for assessing soil algal toxicity. Especially, algal inoculation position is directly related to the efficient use of light for growth. In this study, we assessed the optimal inoculation method of soil algae in soil media. OECD and Lufa 2.2 soils were used as test soils. *Chlorococcum infusionum* of exponentially grown culture was used as a test species. To evaluate applicability of optimal algal inoculation, copper and nickel were used as test chemicals. Algal chlorophyll fluorescence was assessed after solvent extraction. Chlorophyll fluorescence of *C. infusionum* was decreased with the elevated concentrations of copper and nickel. In conclusion, we verified that optimal algal inoculation method was applicable for assessing soil algal toxicity. *This subject is supported by Korea Ministry of Environment as the GAIA project (2014000560001).*

#### WE141

##### **Effect of fluorine on the activities of soil exoenzymes**

Y. Chae, Konkuk University; H. Yoon, Korea Basic Science Institute; Y. An, Konkuk University / Department of Environmental Science

Fluorine is the one of the halogen elements which has great reactivity and electro negativity. It is known to rarely combine with organic matters and combine strongly with clays. This study evaluated the toxicity of fluorine based on the activities of soil exoenzymes including acid phosphatase, arylsulfatase, fluorescein diacetate hydrolase and urease. Test soil harvested in Konkuk University was 2mm sieved and air dried for 7days before use. Sodium fluoride (NaF) was test material because it generally used for fluorine toxicity test. Blank soil were autoclaved for 20 minutes at 120° and treated with 10% formaldehyde. Soil exoenzyme activities were measured in 0, 3 and 10 days using method of endpoint photometric with optical density measurement. As a result, there were concentration-dependent decreases of soil exoenzyme activities in acid phosphatase and arylsulfatase assay and insignificant decreases of soil exoenzyme activities in fluorescein diacetate hydrolase and urease. In conclusion, fluorine affected negatively on phosphorus and sulfur cycles in soil. *This subject is supported by Korea Ministry of Environment as the GAIA project (2013000530001).*

#### WE142

##### **A one-year assessment of biochar effects on key soil invertebrates in a field trial under viticulture**

M. Prodana, University of Aveiro & CESAM / Department of Biology; S. Loureiro, Universidade de Aveiro / Biology; A. Amaro, University of Aveiro / Department of Biology and CESAM; D.N. Nunes Cardoso, CESAM, University of Aveiro / Department of Biology and CESAM Centre for Environmental and Marine Studies; R. Morgado, University of Aveiro / Department of Biology and CESAM; D. Verheijen, D. Keizer, University of Aveiro / Department of Environment and Planning CESAM; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; M. Santos, CESAM & Dept. Biology / Department of Biology and CESAM; A. Bastos, University of Aveiro / Department of Biology Centre for Environmental and Marine Studies CESAM

The application of pinewood biochar (produced at 620°C) to viticulture soils for reducing drought stress in vineyards is the focus of an on-going interdisciplinary field trial, in the wine-producing region of Bairrada (Central Portugal). The main aim of the present study was to monitor the long-term effects of large-scale biochar application on soil invertebrates, their function and/ structure. For that, survival and reproduction of the collembolan *Folsomia candida* and the feeding activity of the isopod *Porcellionides pruinosus* were assessed at time 0, 6 and 12 months, after soil amendment with biochar (4 and 40 t/ha) and biochar mixed with organic waste compost (40 t/ha). No significant differences between treatments and sampling times were observed regarding food consumption of *P. pruinosus*. Moreover, biochar and/or biochar-compost application did not affect survival or the number of produced eggs by *F. candida*. This suggests that pinewood biochar applied to calcareous clay soil under a temperate climate regime up to 40 t/ha, alone or mixed with compost, poses no-to-low risk to representative soil invertebrates, over a 12 month period. By combining two primary non-target organisms and structural and functional endpoints, one can assess and monitor how large-scale biochar amendment can influence soil biota. These results therefore, provide important information and complement physico-chemical parameters for assessing changes in soil quality over time, due to biochar application. Key words: biochar, soil, vineyards, ecotoxicity

#### WE143

##### **Evidence of in vivo cytotoxicity of silver nanowires in earthworms via ingestion exposure**

J. Kwak; Y. An, Konkuk University / Department of Environmental Science  
Although earthworms are key species in the terrestrial ecosystem, researches on the

toxicity of silver nanowires to earthworm species are not reported yet. In the present study, we investigated the acute soil toxicity and *in vivo* cytotoxicity of silver nanowires having two different lengths, then confirmed that *in vivo* cytotoxicities were highly related to ingestion exposure than dermal exposure route. In the individual-level, there are negligible effects of silver nanowires on survival, morphological abnormalities, pathological abnormalities and burrowing behaviors when earthworms were exposed to silver nanowires in the soil. Otherwise, the trends of inhibition of intracellular esterase activities and increasing oxidative stress in the earthworm coelomocytes were analyzed by flow cytometer. In addition, we observed that shorter silver nanowires were more accumulated in the intestines than skin tissues. The results showed that the *in vivo* cytotoxicity could be mainly related to the ingestion exposure route in the earthworm species. *Acknowledgement - This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT and future Planning (2014R1A2A1A11050513).*

## **Effects and accumulation process of organic pollutants and metals in bacteria, phytoplankton and zooplankton (P)**

#### WE144

##### **Growth and physiological effects in *Ankistrodesmus falcatus* and *Microcystis aeruginosa* exposed to nickel stress**

E.B. Martínez-Ruiz, Instituto Politécnico Nacional / Escuela Nacional de Ciencias Biológicas Lab de Hidrobiología Experimental; F. Martínez-Jerónimo, Escuela Nacional de Ciencias Biológicas-I.P.N. / Laboratory of Experimental Hydrobiology

In recent years the release of chemical pollutants to aquatic environments has increased, caused by anthropogenic activities. These pollutants produce acute and chronic effects in aquatic biota, affecting their growth, reproduction and development. The aquatic ecosystems are highly susceptible environments because they act as sink for toxic contaminants. Metals are one of the most common toxic contaminants released to the environment, Nickel is an essential metal who plays an important role in cellular physiology of some eukaryotes and prokaryotes. Some statistics reveal that nickel production worldwide is about 1.589 million tonnes. In Mexico, concentrations in water could be as high as 1.16 mg L<sup>-1</sup>. Phytoplankton is an important community and is the main responsible of organic carbon production and oxygen (through photosynthesis) as the basis of all the trophic webs in aquatic environments, so the toxic effects produced at this level are expected to affect at higher trophic levels. In this study, two primary producers: the green microalgae *Ankistrodesmus falcatus* and the toxigenic cyanobacterium *Microcystis aeruginosa* were exposed to Ni<sup>2+</sup> stress in order to compare their responses. Both microorganisms were separately exposed to different concentrations of nickel, with continuous illumination at 27 °C. The cell density was daily quantified and, at the end of the essay, protein (Lowry, 1951), lipids (Zöllner y Kirch, 1962), carbohydrates (Dubois *et al.*, 1951) and photosynthetic pigments (Wellburn, 1994) were determined; for *M. aeruginosa* phycobiliproteins (Becker, 1994) and cyanotoxins concentration (Enviroligix® kit) were also determined. Both primary producers were very sensitive to low concentrations of nickel, nevertheless the cyanobacterium was the most sensitive; LC<sub>50</sub> values were 17 and 3.7 µg L<sup>-1</sup>, for *A. falcatus* and *M. aeruginosa*, respectively. Additionally, *A. falcatus* showed a decreasing in photosynthetic pigments concentration and in all the determined macromolecules when Ni<sup>2+</sup> concentration increased; *M. aeruginosa* showed an increase in the production of the pigments and macromolecules directly proportional to Ni<sup>2+</sup> concentration. Although Mexican regulation establish that the allowable nickel content in wastewater discharges is 4 mg L<sup>-1</sup> (average monthly), lower concentrations produce significant toxic effects in phytoplankters. For that reason it is necessary to review the maximum limit so as to avoid toxic effects in the aquatic biota.

#### WE145

##### **Toxicity Mechanisms Identification via Gene Set Enrichment Analysis of Time-Series Toxicogenomics Data: Impact of Time and Concentration**

C. Gao, Northeastern University / Bioengineering; D. Weisman, University Of Massachusetts Boston / Department of Biology; J. Lan, Civil Environmental Engineering; N. Gou, Northeastern University / Civil and Environmental Engineering; A. Gu, Department of Civil & Env Engineering / Department of Civil Env Engineering Biotechnology Initiative Program

In recent years, reporter gene expression profiling of whole-cell bacterial arrays has been used for biosensing and real-time toxicity assessment. Bacterial stress responses are of a highly dynamic nature, and exhibit far more temporal complexity than simple dose-response shifts. Current high-throughput bioassays are able record continuous measurement over time and incorporate multiple experimental factors, such as genes, conditions and dose concentrations. However, typical data analysis of these biosensors does not consider their temporal complexity, and therefore, discards valuable information that could potentially identify specific signaling pathways induced by the toxicant. To account for the dynamic response and identify perturbed pathways, this study applied our improved gene set enrichment analysis (GSEA), which is based on a novel time series common principal component analysis (CPCA). This method takes each gene's temporal expression variation into consideration while determining differentially expressed set of genes. By examining the dynamic responses of reporter cells treated with various levels of

mitomycin C, hydrogen peroxide, or lead nitrate, the analysis identified enriched gene sets representing specific pathways, thereby suggesting different mechanisms of toxicity for these chemicals. In addition, we compared this time-sensitive analysis to a time-unaware GSEA and demonstrated the value of the temporal component. This study also investigated the dose dependency of the stress response activation profiles and discussed the impact of time and dose concentration on the gene enrichment analysis results. These results suggest the notion that whole-cell bioassays should account for the cells' complex dynamic responses, thereby implying that both data acquisition and data analysis should look beyond simple traditional endpoint responses when designing high-throughput experiments in toxicogenomics studies.

#### WE146

##### **Distribution character of organic micro-pollutants in fishes from classic schistosomiasis-endemic areas**

G. Zhao, H. Zhou, China IWHR

Pentachlorophenol-Na (Na-PCP) was widely used to kill mollusk in these areas where schistosomiasis is epidemic. HCB has once been used to produce pentachlorophenol (PCP) and Na-PCP. Low-chlorinated phenols (CPs), Chlorobenzenes (CBs) and Polychlorinated biphenyls (PCBs) are the possible impurities of commercial Na-PCP, these organic micro-pollutants will be released into the environment with the use of Na-PCP. To investigate the pollution status of organic micro-pollutants in fish samples from classic schistosomiasis-endemic areas, 105 fish samples were collected. 17 CPs, 12 CBs and 28 PCBs were measured in fish samples using Varian CP3800/300 GC-MS/MS technique. The results show that the contents of PCBs and PCP are 4.59 and 3.39 ng g<sup>-1</sup> dw in the samples, which were moderate and compared with the results reported in the other non-schistosomiasis-endemic areas. However, CBs were the predominant micro-pollutants (GM = 772.7 mg kg<sup>-1</sup> dw; n = 105), the concentration of CBs were significantly higher than those of reported in the other non-schistosomiasis-endemic areas, Dichlorobenzenes (such as 1,2-Dichlorobenzene, 1,3-Dichlorobenzene and 1,4-Dichlorobenzene) are the most predominant congeners. The facts suggest there exists potential health risk due to the pollution of the CBs in these samples; therefore, more in-depth investigations of CBs contamination in these schistosomiasis-endemic areas are needed.

#### WE147

##### **Coupling between phytoplankton and PCB dynamics revealed based on three decades of North Sea and Celtic Sea data**

G. Everaert, Ghent University / Laboratory of Environmental Toxicology and Aquatic Ecology; F. De Laender, Université de Namur ASBL / Laboratory of Environmental Ecosystem Ecology; P. Goethals, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit

We analysed multidecadal field observations (1979–2012) in the North Sea and Celtic Sea with additive models to infer spatiotemporal concentration trends of chlorophyll a and sediment organic carbon, and of polychlorinated biphenyls (PCBs) concentrations in mussels and in sediments. By doing so, we separated long-term changes in PCB concentrations from seasonal variability. Using the inferred seasonal variability, we were able to demonstrate a strong link between PCB concentrations in the sediment and the blue mussel (*Mytilus edulis*) and the chlorophyll a and organic carbon concentrations in sediments. We found that the timing of phytoplankton blooms in spring and autumn correspond to the annual maxima of the organic carbon content and the PCB concentrations in sediments. These results demonstrate the role of seasonal phytoplankton dynamics in the environmental fate of PCBs at large spatiotemporal scales.

#### WE148

##### **Biological treatment and ecotoxicity of wastewater containing corrosion inhibitors**

J. Kalka, The Silesian University of Technology; E. Felis, The Silesian University of Technology; K. Kowalska, M. Nowrotek, J. Surmacz-Gorska, The Silesian University of Technology

**Purpose:** Benzothiazoles (BTs) and benzotriazoles (BTAs) belong to the class of substances, which may be used as corrosion inhibitors. BTs and BTAs are also components of deicing liquids, cutting fluids and hydraulic break liquids. Beyond the industrial applications BTAs are also used in numerous domestic products such as components of dishwasher detergents. The previous study confirmed that BTs are toxic to water plants and aquatic invertebrates. Inhibited growth and reproduction of the crustacea and algae was observed. It has been proven that an important pathway of benzothiazoles and benzotriazoles to the aquatic environment is via wastewater treatment plants. It indicates that their occurrence in the environment is due to diffuse emission for example from consumer products. The environmental concentrations of these substances are various – they range from a few hundred ng/L (e.g. in selected groundwater samples) even up to about 100 mg/L (e.g. in subsoil water). The aim of the study was ecotoxicological evaluation of benzothiazole (BT) and benzotriazole (BTA) influence on microorganisms from municipal wastewater treatment plant as well as *Vibrio fischeri*, a standard model organism. **Methods:** Nitrification inhibition was evaluated according to ISO standard 9509:2006. The purpose of this study was to determine inhibitory effect

of chemical compounds over an exposure period of 4 hours. Nitrifying activated sludge from municipal wastewater treatment plant was used. The concentration range of BT and BTA was 1–100 mg/L. Additionally, the wastewater containing BT and BTA was treated in a biological membrane reactor. The concentration of both chemicals in the influent was equal to 10 mg/L. The acute toxicity test was performed for raw and treated wastewater with the use of Microtox system. Whole effluent toxicity of wastewater was assessed according to EPA procedure. **Results:** It was found that BT was not toxic and BTR was moderately harmful to nitrifying organisms. Both BTA and BT was toxic to *Vibrio fischeri* and EC50 derived during the study was respectively 15,1 and 1,7 mg/L. During the biological treatment, a toxicity of wastewater contaminated with BTA and BT was reduced, however, the dose-response relationship of treated wastewater has changed into inversed U-shape.

#### WE149

##### **Predicting bioconcentration of emerging chemicals using model biomacromolecules**

Y. Ruan, Nankai University / College of Environmental Science and Engineering; H. Sun, China Construction Bank

To understand bioconcentration is indispensable to evaluate the ecorisk of a chemical. Lipid has long been recognized as the main constituent to bind organics, and  $K_{ow}$  is used as an index to evaluate bioconcentration. However, recently, it has been found that lots of emerging chemicals are polar/ionizable, and their bioconcentration can not be explained only by the partition into lipids. Binding to proteins is believed to exert great impacts in bioconcentration. Hence, it is necessary to develop new surrogates other than  $K_{ow}$  to get a precise prediction on bioconcentration. In this study, the distribution coefficients ( $K$ ) of 15 enantiomers of two kinds of chemicals — hexabromocyclododecanes (HBCDs) and  $\beta$ -blockers into several model biomacromolecules (three liposomes and two model proteins) were studied. Meanwhile, their bioconcentration into a microalgae (*Spirulina platensis*) was studied and compared with the  $K$  values. The distribution coefficients into the liposomes ( $K_{lipw}$ ) and the proteins ( $K_{proW}$ ) of the three HBCD stereoisomers had dissimilar orders with their  $K_{ow}$ , indicating some specific interactions other than partition being involved in the distribution into these model biomacromolecules. The  $K_{lipw}$  and  $K_{proW}$  of the four  $\beta$ -blockers were significantly affected by pH with a peak value around neutral pH due to the simultaneous change of their speciation and surface charge of the biomacromolecules. The  $K$  values the four  $\beta$ -blockers are of the same order as their  $K_{ow}$ , however, their discrepancies were smaller than those of  $K_{ow}$ . This indicates that for the hydrophilic  $\beta$ -blockers with low  $K_{ow}$ , they could bind with the biomacromolecules through specific interactions. Raman and fluorescence spectroscopy were checked to get an insight into the microlevel mechanisms, which indicated that HBCDs and  $\beta$ -blockers interacted with the proteins through hydrophobic force and electrostatic interaction, respectively. Correlation between lgBCF in the algae and lg $K$  values revealed that  $K_{proW}$  showed the best predicting capacity for all the 15 enantiomers. The low slope and high intercept in correlation equation indicates that  $K_{ow}$  is not a good indicator for BCF. In all, bioconcentration of HBCDs was an integrated result of sorption by lipids and proteins as well as some other factors such as steric effects; while the binding to proteins played a main role in the bioconcentration of  $\beta$ -blockers.

#### WE150

##### **Removal of Polychlorinated Biphenyls from the Chesapeake Bay by the Commercial Menhaden Fishery**

J.T. Ashley, College of Science Health and Liberal Arts; R. Soroka, A. Sarno, Philadelphia University / College of Science Health and Liberal Arts; L. Zoudeh, Academy of Natural Sciences; D. Velinsky, Academy of Natural Science of Drexel University; J.E. Baker, University of Washington / Center for Urban Waters

The Chesapeake Bay is the largest estuary in the United States, receiving high nutrient inputs from various anthropogenic sources which fuel eutrophication within its waters. Concurrently, the estuary receives significant inputs of PCBs, largely from point sources from its industrialized and urbanized tributaries. Phytoplankton provide organic carbon rich sites for absorption/adsorption of PCBs and represent an important vector for PCB bioaccumulation within higher trophic level organisms such as zooplankton and planktivorous fishes. Atlantic menhaden (*Brevoortia tyrannus*) are pelagic schooling fish found in abundance in the estuary and near coastal regions. As omnivorous filter feeders, juveniles and adults primarily feed on phytoplankton and zooplankton. By filtering vast quantities of planktonic organisms, these fish accumulate polychlorinated biphenyls (PCBs) from this pelagic dietary route. In the past decade, the commercial fishery for Atlantic menhaden landed an annual average of 144 kilotonnes of fish, of which an average of approximately 50% came from fishing efforts within the Chesapeake. This intense reduction fishery processes menhaden into fish oil and meal, high in sought-after omega-3 fatty acids. Using previously reported concentrations of PCBs for U.S. East Coast caught menhaden, the annual removal of PCBs from the Chesapeake Bay was estimated to be between 7 and 30 kg/year. In addition to export to the ocean, burial via sedimentation, and volatilization, removal of PCBs by commercial fishing of menhaden may represent a small, but intriguing loss process to the Chesapeake Bay based on mass balance calculations. Future estimates will include other commercial/recreational fisheries of species such as blue crab and striped bass. Additionally, collection and analysis of Chesapeake Bay menhaden will provide increased confidence in these literature-based estimates of

**WE151****New insights into biological sulfonamide degradation**

B. Ricken, University of Applied Sciences Northwestern Switzerland / Institute for Ecopreneurship; O. Fellmann, University of Applied Sciences and Arts Northwestern Switzerland / Institute for Ecopreneurship; H.E. Kohler, Eawag Swiss Federal Institute of Aquatic Science and Technology; A. Schaeffer, RWTH Aachen University / Institute for Environmental Research; P.F. Corvini, University of Applied Sciences and Arts Northwestern Switzerland (FHNW); B.A. Kolvenbach, University of Applied Sciences and Arts Northwestern Switzerland / Institute for Ecopreneurship

Since sulfonamide antibiotics are among the most frequent administered antibiotics, there is a great interest in environmental fate (Hruska and Franek, 2012). Despite differences regarding abiotic degradation processes, all sulfonamide antibiotics have in common a poor biodegradability. Once released into the environment, even small concentrations are considered to enhance the propagation of sulfonamide antibiotic resistance genes. Just recently, several groups have published their successful isolation of bacteria being capable of partially mineralizing different sulfonamides. Overall, the strains are originating from highly diverse bacterial genera. *Microbacterium* sp. strain BR1, representing one of them, was isolated by our group. To the best of our knowledge, this is the only isolate for which the initial degradation step was described and identified as an *ipso*-substitution (Ricken et al., 2013). The identification of the same heterocyclic moiety as metabolite in different studies leads to the assumption that the underlying degradation pathway among the different bacteria is similar. Furthermore, it was shown that the heterocyclic moiety itself does not possess antimicrobial activities, as the toxicophore group is represented by the sulfanilamide moiety (Majewsky et al., 2014). Different research groups could already prove the ability of bacterial isolates to grow on sulfonamides as the sole carbon source (Jiang et al., 2012; Reis et al., 2014; Ricken et al., 2013). Since the sulfanilamide moiety has to be mineralized, toxic intermediates might be formed, which have been investigated in this study. By degradation experiments of different possible intermediate compounds, and by the identification of formed metabolites by GC-MS analysis, we were able to postulate the downstream pathway during biological degradation of sulfamethoxazole with three novel identified intermediate compounds. The pathway proposed here is directly linked to the previously identified *ipso*-hydroxylation, representing the initial sulfonamide attack, and thus allowing us to present the whole sulfonamide degradation pathway just before the first ring cleavage product. Furthermore, we could show that even though possible toxic intermediates are formed, *Microbacterium* sp. strain BR1 seems to be able to transform them fast enough, circumventing their accumulation resulting in a detoxification of the bacteria cell.

**WE152****Bioaccumulation of organic micropollutants in the cyanobacterium*****Microcystis aeruginosa***

M.A. Stravs, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Environmental Chemistry; F. Pomati, Eawag Swiss Federal Institute of Aquatic Science and Technology / Aquatic Ecology; J. Hollender, Eawag / Environmental Chemistry

*Microcystis aeruginosa* is a cyanobacterial species prevalent in freshwater phytoplankton and among the most important bloom-forming species in eutrophic lakes. Using liquid chromatography - high-resolution mass spectrometry, we investigated bioaccumulation of organic micropollutants of different substance classes in *Microcystis aeruginosa* in laboratory experiments. A set of strobilurin and conazole fungicides was studied. Strobilurin fungicides are used in agriculture, while conazole fungicides have uses in both agriculture and human medicine. For comparison and to further investigate the relationship between log K<sub>ow</sub> and bioaccumulation, a selection of common wastewater-borne and agricultural micropollutants was examined. Highest bioaccumulation was found for pyraclostrobin (log BCF > 5). As a trend, lipophilic substances showed stronger bioaccumulation than hydrophilic ones. The correlation of bioaccumulation to partition coefficient was only weak when considered over all observed substances, but stronger within substance classes (conazoles: R<sup>2</sup> > 0.8, strobilurins: R<sup>2</sup> > 0.6). In some instances (e.g. Trifloxystrobin) formation of transformation products was observed in the presence of *Microcystis*. These results indicate a potential importance of cyanobacterial phytoplankton in the fate of organic micropollutants in lakes. In particular during bloom events, cyanobacterial biomass may be a relevant compartment for partitioning of micropollutants.

**WE153****Organochlorine pesticides in eels, Conger myriaster, from Korean coastal waters**

M. Choi, I. LEE, D. Hwang, R. Jung, National Fisheries Research and Development Institute

As eels have a high fat content, lipophilic contaminant concentrations can be relatively high. Therefore, monitoring of contaminants in eel seemed very informative from a human health point of view, as this type of fish could serve as a worst-case scenario. In particular, eel has some remarkable properties that make it a very attractive biomonitor. Eels (*Conger myriaster*, 30-35 cm length) were collected from Korean coastal waters in April-August, 2014, in order to investigate

contamination status of organochlorine pesticides (OCPs) in Korean coastal waters. OCPs (4 HCHs, HCB, heptachlor and its epoxide, 5 chlordanes, and 6 DDTs) were analyzed in eel samples. This is the first study to investigate residue levels and accumulation patterns of OCPs in eels from Korean coastal waters. Among OCPs, DDTs were the most frequently detected and showed the highest concentration. The next greatest concentrations were HCB and chlordanes. DDTs ranged from 2.73 to 14.4 ng/g wet wt and contributed to 88% of the total OCPs. p,p-DDE was the main compound in DDTs, and its proportions accounted for 70%. HCB ranged from 0.14 to 1.26 ng/g wet wt and chlordanes ranged from less than detection limits to 1.12 ng/g wet wt. *trans*-nonachlor was the most abundant in chlordanes. There were significant differences in OCPs concentrations among sampling areas. Higher concentrations of DDTs, chlordanes, and HCB were found along industrialized and urbanized coasts. Interestingly, the concentration of DDT was the highest, and the ratio of (DDE+DDD)/DDTs was the lowest in the Yellow Sea. It suggests that this area has been input and polluted by fresh DDTs.

**WE154****Off-site effects of wildfires: Assessment of the effects of ash and soil on a freshwater microalgae**

N. Abrantes, University of Aveiro / CESAMDAO; A. Kieskamp, University of Aveiro / CESAM Department of Environment; V. Silva, Universidade de Aveiro / Department of Environment and Planning and the Centre for Environmental and Marine Studies CESAM; F. Goncalves, S. Frankenbach, J. Serôdio, University of Aveiro / CESAM Department of Biology; J. Keizer, Department of Environment Centre for Environmental and Marine Studies CESAM University of Aveiro Aveiro Portugal

Wildfires are a common phenomenon in Portugal, with an average of 110,000 hectare burned every year. Wildfires physically degrade land, promoting runoff and erosion the consequent washout of ashes. This leads to an increase of suspended solids in aquatic ecosystems which may decline the aquatic habitat quality by limiting habitat availability and light penetration. In addition, ashes can contain metals and PAHs (Polycyclic Aromatic Hydrocarbons), which are known as toxic compounds inhibiting growth, development and reproduction of aquatic organisms like green microalgae. To analyze the off-site effects of soil and ash on primary production, a laboratory experiment was performed to estimate the effect of pure soil, pure ash and a mix of both on the cell density, chlorophyll *a* content and maximum quantum yield of the microalgae *Raphidocelis subcapitata*. For each treatment dilutions of 50% and 25% (diluted with MBL medium) were tested as well as a filtered 100% solution. Results showed that cell density and chlorophyll *a* content were negatively affected by only the highest concentrations of the mixed treatment and by the 50% diluted pure ash treatment, if compared to the control treatment. This observation was probably caused by ash toxicity rather than by light limitation, since cell density and chlorophyll *a* content of the soil treatments were not significantly affected. The maximum quantum yield was not influenced, except by all filtrated treatments. Remarkably, the maximum quantum yield was significantly higher in filtrated treatments compared with control and other treatments. It was also shown that the 100% filtrated treatments lead to a significant higher cell density. This suggests that toxic compounds were filtered out and therefore could not affect the measured parameters; in general, PAHs have a low water solubility. The high values for cell density and maximum quantum yield for the filtrated treatments was probably caused by the entry of ashes resulting in higher nutrient concentrations. Light limitation seems not to affect the measured parameters in the short term of this 72 hour laboratory experiment. However, the possible effects after a long term exposition cannot be discarded. Yet, the short term toxic effect of ashes in a key group of aquatic food webs reinforces the need to act immediately after a forest fire and reduce runoff and erosion in order to prevent ashes from entering aquatic ecosystems.

**WE155****Size matters: Effects of Cu and Cd on the growth, viability, cell volume and photosynthetic activity of the tropical freshwater phytoplankton *Chlorolobion braunii***

P. Echeveste, J. Carmo Silva, Universidade Federal de São Carlos / Department of Botany; C.J. Galbán, Sustainability Research Centre / Department of Ecology and Biodiversity; A. Lombardi, Universidade Federal de São Carlos

Copper and Cd are two of the most ubiquitous trace metals in nature, including freshwater ecosystems. In these environments, their cycling is influenced by phytoplankton, which primary production sustains aquatic life. Copper is an essential metal involved in the oxygen transport, while Cd has no apparent biological functions, although in some limiting conditions it can substitute Zn. Thus, Cu and Cd are usually classified as “nutrient” and “poison”, respectively, although the dose may determine its real behaviour. The present work analyzes the impact of environmentally relevant concentrations of Cu and Cd on the growth, viability, cell size and photosynthetic activity of the tropical freshwater phytoplankton *C. braunii*. Growth was significantly impaired by Cu and Cd, with EC50 occurring at 33.6 and 1.6 µM, respectively. At concentrations where no significant differences in cell abundances were observed, cell death was already induced, as observed by the increase in the percentage of dead cells, with EC50 occurring at 17.2 µM Cu and 1.1 µM Cd. Regarding the oxygen-evolving complex (OEC) of photosystem II (PSII), Cu had no significant effects on PSII maximum quantum yield (Φ<sub>M</sub>) and the operational quantum yield (Φ'<sub>M</sub>), while Cd

significantly impacted  $\Phi'_M$ , with EC50 occurring at 18.4  $\mu$ M. The photochemical fluorescence quenching (Qp) and non-photochemical quenching (Qn) responded differently to Cu and Cd. A significant decrease of Qp was observed after Cd addition, but not for Cu, which showed almost no variation. In contrast, Qn values significantly increased after both metal additions, gradually in the case of Cd and after addition of high concentrations in the case of Cu. Non-photochemical quenching due to heat dissipation (NPQ) significantly increased in response to both metals, being more pronounced in the case of Cd. Cell volume increased as metal concentrations increased, pointing not to an individual increase in cell volume, but rather to a selection of larger-sized strains tolerant to metal exposure. Overall, *C. braunii* was more sensitive to Cd than Cu, with growth and viability being more sensitive than maximal and effective photosynthetic efficiencies, although non-photochemical quenchings were severely damaged by both metals.

#### WE156

##### Assessment of exposure to Persistent Organic Pollutants in fish (*Oreochromis* sp) in dams of Mexico

J. Mejía Saavedra, Facultad de Mecina / Facultad de Medicina; R. Flores Ramirez, M. Barrera Perez, L. Batres Esquivel, D. González Mille, C. Ilizaliturri Hernandez, G. Espinosa Reyes, Universidad Autonoma de San Luis Potosi

Persistent Organic Pollutants (POPs) are organic compounds of anthropogenic origin, resistant to degradation, and can be mobilized and deposited far from the site of manufacture and use. In the ecosystem can bioaccumulate and biomagnify through the food chain affecting the health of wildlife. Are considered carcinogenic, mutagenic, immunosuppressive, endocrine disruptors and nervous system depressants. It has registered the presence and effects in different organisms in the world. Mexico has demonstrated the presence of POPs in different environmental compartments. Dams can be a site of accumulation of these compounds, because the stored water comes from rivers and runoff crawl contaminants on its way from industries, cities and agricultural areas, which over time accumulate in sediments and aquatic organisms. The present study was undertaken to investigate the presence of POPs in some dams of Mexico, through its determination in muscle of fish (*Oreochromis* sp). POPs extraction was performed using ultrasonic probe assisted extraction, detection and quantification by gas chromatography-mass spectrometry. In the muscles of fish the presence of some organochlorine pesticides (Aldrin, HCH, DDT, DDE) and polychlorinated biphenyls (PCBs) was recorded. Acknowledgements: CONACYT-SEMARNAT-2008-1-108334

#### WE157

##### Effects of climate change induced physical disturbance on sediment deposited pollutants and their interactions with bacteria in the Northern Baltic Sea

C. Gallampos, Umea University / Chemistry; P. Haglund, Department of Chemistry; O. Rowe, Department of Ecology and Environmental Science Umeå University

Christine Gallampos<sup>1</sup>, Peter Haglund<sup>1</sup>, Owen Rowe<sup>2,3,1</sup> Chemistry Department, Umea University, Umea, Sweden <sup>2</sup> Department of Ecology and Environmental Science, Umea University, Umea, Sweden <sup>3</sup> Guest researcher: Department of Food and Environmental Sciences, Division of Microbiology and Biotechnology, Viikki Biocenter 1, University of Helsinki, Helsinki, Finland. The Baltic Sea is a semi enclosed sea with large areas of polluted and anoxic sediments. Wood industry associated fiber deposits often contain 2,4-Dichlorophenol, 2,4,6-trichlorophenol, naphthalene, acenaphthene, fluorene and phenanthrene, particularly in northern coastal regions. Predicted climate change scenarios for the northern Baltic Sea indicate higher wind speeds and, in addition, land rises at a rate of about 1 cm per year. Such changes could disturb shallow sediments, causing oxygenation and resuspension. These physical changes and associated increases in microbial activity will likely influence the transport and fate of contaminants. In this study, glass microcosms containing a sediment layer, spiked with a cocktail of contaminants (as above), and overlaying seawater were used to investigate the effects of the predicted climate change. Microcosms were incubated *in-situ* at 11°C (temperature of seawater at the sediment surface when sampling) under two different treatment conditions: 1) current conditions - sealed and undisturbed or, 2) climate scenario – lightly oxygenated and physically disturbed (gentle shaking once per week). The impact of the chemicals on the microbial communities, and the microbial action on the chemicals, was both investigated. We aim to report changes in bacteria abundances and community structure and link this to metabolite appearance, and examine possible effects of metabolites on the bacteria.

#### WE158

##### Toxicological effects of organic and inorganic compounds on zooplankton and phytoplankton estuarine and marine species

V. Filimonova, University of Aveiro, Department of Biology & CESAM / Department of Biology CESAM; F. Goncalves, University of Aveiro CESAM / Department of Biology; J.C. Marques, IMAR-Institute of Marine Research, Department of Life Sciences, University of Coimbra / Department of Life Sciences; M. De Troch, Ghent University / Biology department; A.M. Gonçalves, Biology In the last decades contaminants' discharges are one of the themes that concerned the scientific community and received special attention by media because of the threat and adverse effects that may cause in aquatic ecosystems. The pollutants that cause most damage to the ecosystem originated from industry and mining including

toxic substances such as metals and organic pollutants. Phytoplankton and zooplankton are widely used in the determination of environmental impacts due to their key position in the food chain. Three biological models (marine diatom *Thalassiosira weissflogii*, estuarine calanoid copepod *Acartia tonsa* and marine brine shrimp *Artemia franciscana*) were used to constitute a simple trophic food chain under lab conditions. This work aims to assess the acute and chronic effects of two chemical stressors - the herbicide Primextra® Gold TZ and the metal Copper (Copper (II) Sulfate Pentahydrate), to the three planktonic species. Primextra® Gold TZ is the most used herbicide in corn crops fields and one of the 20 best-selling herbicides in Portugal; Copper is mainly used in pesticides' formulation. The toxicity of the herbicide and the metal were assessed focusing on the growth inhibition of the microalgae *T. weissflogii* (chronic tests, 96h) and the immobilisation (acute tests, 48h) of *A. franciscana* and *A. tonsa*, without food. Vessels were checked for immobilized individuals, at 24 h and 48 h. ECx values were estimated through either Probit analysis or non-linear estimation using the logistic equation. Our study confirms the herbicide and the metal are highly toxic to the marine diatom *T. weissflogii* (EC<sub>50</sub>=0.0078 mg/L and EC<sub>50</sub>= 0.3834 mg/L, respectively) and to the calanoid copepod *A. tonsa* (EC<sub>50</sub>=0.925 mg/L and EC<sub>50</sub>=0.234 mg/L, respectively) but slightly toxic to nauplii of brine shrimp *A. franciscana* (EC<sub>50</sub>=20.35 mg/L and EC<sub>50</sub>= 18.93 mg/L, respectively). The higher tolerance of the brine shrimp may be explained by the morphological feature of *A. franciscana*. The results of this work suggest that discharges of Primextra® Gold TZ or other pesticides mainly composed by copper proceeding from agricultural practices into aquatic ecosystems damages the natural planktonic species populations, with severe repercussions for higher trophic levels. Therefore, our results underline the importance of clarifying the mode of action and metabolic pathways of these compounds on non-target species.

#### WE159

##### Effect of Arsenate (AsV) on the biomarkers of an aquatic macrophyte *Myriophyllum alterniflorum* in eutrophic and oligotrophic conditions

M. Krayem; P. LABROUSSE, V. Deluchat, M. Rabiet, K. CLeries, J. Lenain, Université de Limoges; V. Kazpard, Z. Saad, Lebanese university

Alternate watermilfoil, *Myriophyllum alterniflorum* is an aquatic macrophyte found in the Limousin rivers (France) whose potential for biomonitoring of metal pollution has been demonstrated. The objective of the present study carried out *in vitro* in a closed system is to identify biomarkers for an early detection of the pollution by a metalloid in eutrophic and oligotrophic conditions. To achieve this goal, a synthetic medium of similar composition to the waters of the River Vienne is prepared. The morphological development of Watermilfoil is monitored for 30 days, with or without contamination by 100  $\mu$ g /l As V. In addition, the mineralization of fresh material and the analysis of biomarkers (chlorophylls, photosynthetic and respiratory intensities, H<sub>2</sub>O<sub>2</sub> ...) are performed after 21 days. Preliminary results indicate that arsenic present deleterious effects on the respiratory and photosynthetic activities, on the osmotic potential and on the pigments content of the plant in both conditions, and on the concentration of H<sub>2</sub>O<sub>2</sub> only in eutrophic condition. The growth of ramification was reduced in eutrophic medium and totally inhibited in oligotrophic medium. In addition, the highest accumulation of arsenic was found in the plant's roots. After these *in vitro* experiments, complementary experiments in mesocosms are in progress. Further, *in situ* experiments including watermilfoil reimplantation should help to refine these results. Keywords: *Myriophyllum alterniflorum*, éléments traces métalliques, spéciation, biomarqueurs.

#### WE160

##### Effect of an herbicide on the growth rate of freshwater primary producers

A.M. Gonçalves, Biology; D.V. Barroso, University of Coimbra / Department of Life Sciences; T. Vidal; J.C. Marques, IMAR-Institute of Marine Research, Department of Life Sciences, University of Coimbra / Department of Life Sciences; F. Goncalves, University of Aveiro CESAM / Department of Biology Pesticides are widely used to control pests and diseases in crop production. Among these agrochemicals, herbicides are commonly applied on crops to control adventive infestations. Once in the aquatic system, these chemicals may disturb aquatic organisms leading to underperformance of the most sensitive species, causing ecosystem unbalance. Aquatic plant toxicity tests are frequently conducted to assess environmental risks and to determine the potential impact of contaminants on primary producers. Among aquatic organisms, *Chlorella vulgaris*, *Raphidocelis subcapitata* (green freshwater microalgae) and *Lemna minor* (aquatic vascular plant) are commonly used in phytotoxicity tests because of their small size, their high reproductive rate and the facility with which organisms handled facilities. The sensitivity of *C. vulgaris*, *R. subcapitata* and *L. minor* exposed to the herbicide Primextra® Gold TZ was assessed. Algae and duckweed were exposed during 96h and 7 days for growth rate, respectively, according to protocol guidelines. *C. vulgaris* showed to be the most tolerant species, (EC50=2.541 mg/L), whereas *R. subcapitata* was the most sensitive species (EC50=0.065 mg/L). The EC50 values determined for *L. minor* was 0.293 mg/L. The results of this work suggests that the application of this herbicide for weed control in agricultural practices must be done carefully, since any disturbance affects primary producers species which may have severe repercussions on higher trophic levels. Furthermore, and according to preliminary works, microalgae seems to be more nutritive (in fatty acids contents) than *L. minor*. Therefore, it can be predicted that, at an extreme usage event of the

herbicide, the food quality and availability to higher trophic levels may be threatened.

Fornasier, Centro per lo Studio delle Relazioni tra Pianta e Suolo / Consiglio per la Ricerca in Agricoltura; S. Sulowicz, University of Silesia / Department of Microbiology; D. Karpoyzas, University of Thessaly / Department of Biochemistry and Biotechnology; M. Trevisan, Università Cattolica del Sacro Cuore / Institute of Agricultural and Environmental Chemistry

Trifloxystrobin, methyl-(E)-methoxyimino-(E)-a-[1-(a,a,a-trifluoro-m-tolyl)ethylideneaminoxyl]-o-tolyl acetate, is a strobilurin fungicide, a new class of substance that is included in the Quinone outside inhibitors (QoIs) fungicide groups. Trifloxystrobin is used for control of various diseases of fruits and vegetables. The major metabolite of trifloxystrobin in soil is CGA 321113 (E,E)-Methoxyimino-2-[1-(3-trifluoro methylphenyl)-ethylideneaminoxymethyl]-phenyl-acetic acid). This acid metabolite is included in the residue definition for risk assessment in plant commodities. Little is known about the impact of trifloxystrobin or its main CGA 321113 metabolite on the structure and function of the soil microbial community. For addressing associated knowledge gaps concerning the potential toxicity of trifloxystrobin and CGA 321113 on the soil microbial community we studied the effects of four dose levels (namely x0, x1, x10 and x100 the recommended dose) of trifloxystrobin in soil in a microcosm approach. Key soil microbial enzymatic activities and total bacterial diversity shifts using Illumina sequencing of the 16S rRNA gene amplicons were screened and compared with the dissipation data of trifloxystrobin and formation/degradation of CGA 321113. Dissipation assessment revealed that the half-life of trifloxystrobin in soil was less than 5 days, at all application rates, and the highest formation rate of the metabolite was observed in the first 15 days. Trifloxystrobin was correlated positively with the potential nitrification activity (PNT). No effect of trifloxystrobin on the measured extracellular enzyme activities (acid-phosphatase, beta-glucosidase, leucine-aminopeptidase, phosphomonoesterase, phosphodiesterase, chitinase) could be extrapolated according to the performed statistical analysis. However, distance based redundancy analysis (db-RDA) showed a time effect on enzymatic activities within the different trifloxystrobin application rates. Bacterial diversity analysis is on the way and the complete dataset will be presented during the conference.

##### **Determination of selected steroid hormones in some farmland pond, surface water and waste water channel Cape Town environment using HPLC**

O.S. Olatunji, Cape Peninsula University of Technology / Chemistry; B.O. Opeolu, Cape Peninsula University of Technology / Faculty of Applied Sciences; O.S. Fatoki, B.J. XIMBA, Cape Peninsula University of Technology / Chemistry

Steroid hormones are widely used in livestock farming such as poultry, cattle farming, and in veterinary and human medicine. Over two-third of the drugs are not used, hence it is excreted in urine and faecal wastes in the form they are administered, or as metabolites with strong resemblance to the parent compound. Consequently, they are found in different environmental matrices such as water. Exposure to residues of steroid hormones was reported to disrupt the endocrine systems even at low concentration. This study evaluated the concentration levels of selected steroid hormones in selected water streams, including farmland pond, surface water and wastewater treatment plant effluent in Cape Town. Water sample were collected in nitric acid pre-washed amber coloured bottles from columns of some water receiving pond within some animal rearing farms located in Athlone, Grassy Park and Phillippi farms, and Blue Downs in Cape Town environment. The samples were prepared using standard methods. Steroid hormones were recovered from the samples in 50% methanol using solid phase extraction (HLB), cleaned and concentrated to 2ml under nitrogen stream for analysis. The hormones were separated, detected and quantified for the estradiol, bisphenol-A and estrone using UHPLC-DAD. The results showed that the concentrations of estradiol and estrone in all the water samples were variable, while Bisphenol-A did not occur at detectable levels. The concentration of estradiol and estrone ranged between 0.0126 – 0.0131 µg/L (0.0128±0.0021 µg/L), 0.0154 – 0.0159 µg/L (0.0157±0.0021 µg/L), respectively. Estradiol in water of may be the result of run off from the cattle on the farm in Blue Downs, with the levels detected in pond 1 higher than in pond 2 which is contact with a stream. Contrary to expectation, the Athlone waste water treatment plant outlet water had higher estradiol concentration compared to the inlets water. The water treatment procedure may have exacerbated their levels. The concentration levels of steroid hormones in all the water sample tested were observed to be slightly below the 0.02 mg/L of estrogen suggested by the SADC Ministry of

Health, except for estradiol.

#### WE163

##### **A study of analyte recovery as a function of analyte concentration and sample storage time using headspace solid-phase micro-extraction (HS SPME) coupled with GC-ECD**

F.M. Dunnivant, Whitman College / Chemistry

Headspace Solid-Phase Microextraction (HS SPME) has been shown to recover pesticides and PCBs from aqueous samples at the expected ultra-trace levels (parts per quadrillion) of alpine lakes. Several variables of the HS SPME technique have been adequately evaluated including water temperature and length of fiber exposure, but surprisingly analyte recovery as a function of analyte concentration and storage time has not been studied. This investigation evaluates the recovery of the chlorinated hydrocarbons 4,4'-dichlorodiphenyltrichloroethane (p,p'-DDT), 2,4'-dichlorodiphenyltrichloroethane (o,p'-DDT), 4,4'-dichlorodiphenyldichloroethane (DDD), 2,4'-dichlorodiphenyldichloroethylene (o,p'-DDE), chlorthal-dimethyl gamma-hexachlorohexane (lindane), heptachlor, and trans-nonachlor. Evaluated concentrations ranged from parts per quadrillion to parts per billion in spiked water samples and data indicate that recoveries in the ppq range can be as low as ten percent. In light of the low SPME recoveries in the ppq range, several previously reported data sets for chlorinated hydrophobic analytes measured in alpine lakes need to be re-evaluated. The HS SPME technique was further used to determine the concentration of chlorinated pesticides in several U.S. alpine lakes.

#### WE164

##### **Automated Derivatization, SPE Cleanup and LC-MS/MS Determination of Glyphosate and Others Polar Pesticides**

J. Stahl-Zeng, AB SCIEX; D. McMillan, Sciex; A. Sage, ABSCIEX / marketing

Glyphosate is a common broad-spectrum systemic herbicide used widely to kill weeds especially annual broadleaf weeds and grasses known to compete with crops. There is an interest in the reliable and sensitive quantitation and identification of glyphosate residues, its metabolite AMPA, and the related glufosinate in food and water. Commonly large volume injection into ion chromatography or LC systems based on HILIC followed by sensitivity MS/MS detection is used for analysis. However, interference can influence results in complex samples since the method does not use any cleanup. Derivatization techniques can be used successfully. The method presented here uses derivatization with FMOC-Cl followed by automated SPE cleanup using a Gerstel front-end and detection using LC-MS/MS with an AB SCIEX QTRAP 4500 system. Limits of quantitation in food were found below the target 100 µg/kg allowing dilution to minimize potential ion suppression. In drinking water samples glyphosate was quantified below 0.1 µg/L. Linearity of over three orders of magnitude with  $r > 0.999$  was observed with excellent reproducibility because of the complete automation of the sample handling procedure.

#### WE165

##### **Challenges in Analytical Method Development and Validation for Trace-Level Dimethylsilanediol in Water**

S. Xu, Dow Corning Corporation / Health and Environmental Sciences

Dimethylsilanediol (DMSD) is not a major ingredient of any commercial products. However, it can be produced in soil and water by hydrolysis of methylsiloxanes in the environment. Due to widespread application of methylsiloxanes in commercial products and its demonstrated degradation in soil and water, the occurrence of trace-level DMSD may be expected in some of the environmental media such as water. Due to lack of sensitive analytical methods, such data are not available in literature. In our attempt to fill the data gap, we have evaluated and developed various analytical methods for silanols analysis. This presentation focuses on challenges in development and validation of GC/MS methods for trace-level DMSD in water. The identified challenges include the difficulty to isolate DMSD from water, the detrimental effect to the instrumental components from residual water, high background contaminations and poor chromatography of the extracted DMSD. Both pre-column derivatization and direct analysis methods were evaluated for overcoming the above challenges to achieve adequate sensitivity and accuracy. As the result of those evaluations, a method consisting of solid-phase extraction, reactive water removal and direct GC/MS analysis has been developed and validated for natural water at a method detection limit for DMSD close to 10 µg L<sup>-1</sup>.

#### WE166

##### **Analytical Method for Trace-Level Trimethylsilanol in Water**

S. Xu, Dow Corning Corporation / Health and Environmental Sciences; B. Kropscott, Dow Corning Corporation

Organosilanols such as trimethylsilanol and dimethylsilanediol are two reactive compounds and ultimate hydrolysis products of a group of high-production-volume per-methylated organosiloxanes, in the environment. The distribution of these silanols in various environmental media is, therefore, very important for a complete understanding of the fate and effects of siloxanes. Although the environmental information on siloxanes is exponentially increased in recent years, the data on environmental occurrence of silanols are scarce. This is largely due to the lack of sensitive methods for accurate analysis of low level silanols in the environmental

media. In the present studies, we have developed highly sensitive methods for accurate analysis of trace-level silanols in water. This presentation will focus on the development and validation of a method capable of analyzing sub-ppb level TMS in natural water based on solid-phase extraction (SPE) coupled with gas chromatography/mass spectrometry (GC/MS).

#### WE167

##### **Study of Chemcatcher® kinetic uptake for herbicide: batch experiment and flow laboratory calibration**

I. Imtiaz, Ecole des Mines d'Alès / Laboratoire LGEI; a. togola, BRGM / Laboratory Division; R. Greenwood, University of Portsmouth / School of Biological Sciences; C. Gonzalez, Ecole des Mines d'Alès / LGEI

The widespread use of pesticides in agriculture activities leads to the contamination of surface and ground waters caused by drift, runoff, drainage, and leaching of soils. The pollution of water by pesticides is an issue of environmental concern, owing to the increasing number of pesticides detected in water and to the establishment of directives such as Directive 2000/60/EC which defined a framework for the protection of waters bodies. A number of pesticides belonging to the classes of phenylureas, triazines and chloroacetanilides, are mentioned as priority substances. Passive sampling techniques, which rely on the diffusion of pollutants from the sampled medium to a receiving phase, have gained in popularity because they can provide time-weighted average (TWA) concentrations of pollutants when used in integrative mode. Since these devices accumulate pollutants over a period of time, they can, depending on the compound-dependent sampling rate, provide a preconcentration of analytes, thus enabling the detection of compounds present in the water at very low levels that are not always detected in grab samples of water. In order to calculate the TWA concentration of a pollutant in water, it is necessary to measure the mass of analyte accumulated in the sampler, the deployment time, and to know the corresponding sampling rate  $R_s$ . The latter is determined, in particular for Chemcatcher®, in laboratory scale calibration experiments, where the samplers are exposed for a defined time to a constant analyte concentration in water. This work aims to compare the sampling rate  $R_s$  obtained through flow pilot calibration and batch experiments for 20 polar herbicides. The uptake of herbicides by the Chemcatcher® (C18 as receiving phase and PES membrane) has been determined by the both methods. Based on a kinetic approach two methods of calculating  $R_s$  are proposed; one based on batch experiments, and the other on through flow laboratory calibration. The results of the batch experiment are in good agreement to those of flow laboratory calibration and the former approach has the advantage of simplifying the calibration procedure for determining  $R_s$ . However, since hydrodynamic conditions can vary widely in the field, caution is needed when using laboratory based calibration data in deployments.

#### WE168

##### **Zwitterionic based online solid phase extraction liquid chromatography tandem mass spectrometry for rapid environmental trace analysis of the very polar and hydrophilic antiviral drug zanamivir**

H.S. Söderström, Umea University; G. Fedorova, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses Vodnany Czech Republic; K.M. Blum, Umea University / Department of Chemistry; J. Pulit-Prociak, Cracow University of Technology; A. Gillman, Uppsala University; J. Jarhult, Uppsala University / Section of Infectious Diseases, Department of Medical Sciences; P. Appelblad, Merck Millipore Sweden; R.H. Lindberg, Umea University / Department of Chemistry

Hydrophilic interaction liquid chromatography (HILIC) enables, in contrast to conventional reversed phase liquid chromatography (RP-LC) unless ion-pairing is used, significant retention and hence trace analysis using liquid chromatography mass spectrometry (LC/MS) of very hydrophilic and polar analytes (VHPAs). In environmental trace analysis, offline solid phase extraction (SPE) is generally used for extraction of VHPAs from aqueous samples but automated online SPE has been used and are become increasingly popular as it is time-effective and improve sample throughput and minimize manual labor. Neuraminidase inhibitors (NAIs) are antivirals used for treatment of influenza A and B. Zanamivir (Relenza®) (Za) was the first developed NAI and is excreted almost 100% unchanged from treated humans. Za is highly hydrophilic and polar, distributed to the environment via wastewater and relatively photostable. This has caused concerns as wild water birds, the natural hosts of influenza, tend to swim near outlets of sewage treatment plants and thus can get exposed to water containing the potential highest concentrations. This can induce environmental resistance development in avian influenza viruses which in worst case could cause an antiviral-resistant pandemic. The usage of Za today is limited but in cases of wide-spread resistance to the predominantly used antiviral the NAI oseltamivir (Tamiflu®), the usage of Za can increase. In this study, an online SPE/LC using a bonded zwitterionic stationary phase (ZIC-HILIC) and tandem mass spectrometry (MS/MS) method was developed. Furthermore, an internal standard (IS) calibration method capable to quantify Za in Milli-Q water, surface water, sewage effluent and sewage influent was evaluated. Due to the nature of HILIC, aqueous samples needs to be treated pre extraction. In this study by dilution with acetonitrile (ACN) and addition of formic acid (FA). Experimental design was used to find an optimum sample pre-treatment of 95/5 v/v ACN/ aqueous sample and then 1% FA. Furthermore, the developed method showed acceptable linearities ( $r^2 \geq 0.994$ ), filtration recovery ( $\geq 91\%$ ), and

repeatabilities ( $RSD \leq 16\%$ ), and LOQs values which were acceptable and environmentally relevant ( $\leq 20 \text{ ng L}^{-1}$ ). The evaluation also showed that MilliQ water, surface water and sewage effluent can be stored for 20 days in +4 and -20 °C (losses  $\leq 12\%$ ) while sewage influent should be stored at -20 °C to avoid significant Za losses.

#### WE169

##### **Validation of a method for the determination of chlorothalonil in seawater.**

G. Zanuto, University of São Paulo USP; L.R. Diniz, T.M. Oliveira, São Paulo State University Institute of Chemistry; E.M. Vieira, Sao Paulo University / Departamento de Química e Física Molecular

The formulation of marine antifouling coatings can include, inorganic, organic or organometallic substances, which have the function to inhibit the attachment of organisms (*biofouling*) that can compromise the mechanical structure, fuel consumption and reduce the useful lifetime of ship's hulls. With the restrictive regulation of the TBT, new compounds have been incorporated along with copper the composition of paints. In Brazil there are few studies focusing on such compounds. These substances are used separately or in mixtures, in the latter case to enhance the biocide action of painting. Recent studies report that increased use of antifouling bottom paints may cause certain environmental problems.

Chlorothalonil (2,4,5,6-tetrachloroisophthalonitrile) is a fungicide belonging to the group of isofthalonitrils with a molecular weight of  $265.9 \text{ g mol}^{-1}$ , has a logKow of 2.88 and a BCF of 264, which indicates that is not considered bioaccumulative, however degrades to a persistent metabolite ecotoxic. The half-life for chlorothalonil is in the range 4-150 hours, while the half-life for the metabolite is greater than 30 days is therefore considered persistent as it forms persistent toxic degradation products. Chlorothalonil started being used also as booster antifouling paints third generation and despite other uses as a wood protectant, pesticide, acaricide, and to control mold, mildew, bacteria and alga, the presence of chlorothalonil in samples of seawater may indicate its source is associated with your use as booster biocide. Target compound was isolated by liquid-liquid extraction (LLE) and then analyzed by analyzed by HPLC-DAD using analytical column C18 Nucleosil (150 x 4.6mm, 5  $\mu\text{m}$  endcapped), and gradient mobile phase containing acetonitrile and phosphoric acid 0.1% 70:30 at  $1.0 \text{ mL min}^{-1}$ . Detection and quantification are made at a wavelength of 231 nm. Preliminary results were the establishment and validation of the analytical conditions for quantification of chlorothalonil, for determination of sensitivity and linearity of the method have been established parameters of the calibration curve for concentrations between 0.1 and  $4 \mu\text{g mL}^{-1}$ . The correlation coefficients (R) obtained, was 0.99 and limit of detection and limit of quantification 1.0 and  $2.0 \mu\text{g L}^{-1}$  respectively Keywords: Antifouling paints, chlorothalonil, LLE.

#### WE170

##### **The spatial and temporal pesticide and metal contamination in Dilek National Park, Turkey**

C. Turgut, ADU; L. Atatanir, Adnan Menderes University; M. Yalçın, Adnan Menderes University / Faculty of Agriculture; T. Cutright, University of Akron / Department of Civil Engineering; A. Gavcar, Adnan Menderes University / Faculty of Agriculture Lab Environmental Toxicology

**National parks are used worldwide as means to protect the ecological integrity of unique ecosystems. Dilek National Park in Western Turkey is a protected habitat for several endangered and threatened species. In an attempt to protect the endangered species, the park was classified as a World Heritage Preserve. Even, with this change, the animal and flora variety are still at risk from previous metal and pesticide pollution. Water and sediment samples were collected at two different sampling depths. The park contaminated 16 different organochlorine pesticides, with more pesticides detected in sediments than in water. The most prevalent pesticides in 0-30 cm depth were DDT, heptachlor and endosulfan. Inorganic elements were found in all sediment samples. Sodium had the highest aqueous concentration, while Cu, Fe, Mn and Zn were present at levels significantly lower than the chronic exposure criteria. These pesticides could be a long-term contamination source that enters the food web used by the very species the park is trying to protect. The main contamination sources of metals seem to be Great Meandrous River. More studies are needed to develop a protection and remediation strategy for Dilek National Park.**

#### WE171

##### **SEASONAL VARIATIONS IN CONCENTRATION OF PARABENS ON MOGI RIVER IN BRAZIL**

C.A. Galinaro, Universidade de Sao Paulo / Chemistry; F.M. Pereira, University of São Paulo USP / engineering of materials; E.M. Vieira, Sao Paulo University / Departamento de Química e Física Molecular

##### **Seasonal variations in concentration of parabens on Mogi River in Brazil**

Carlos A. Galinaro, Fabiana M. Pereira and Eny Maria Vieira\* IQSC - Universidade de São Paulo - Brazil. \*e-mail eny@iqsc.usp.br. **Keywords:** Parabens, surface water, and DLLME-HPLC-DAD. Parabens are preservatives extensively used to prevent microbial growth in many common care products. Most parabens are frequently found in river water at concentrations reaching from  $\text{ng L}^{-1}$  to  $\text{mg L}^{-1}$ , and their levels depend mainly on the extent of water dilution resulting from rainfall. Discharge of treated wastewater effluent into the river was found to

be the main cause of water contamination with parabens. Dispersive liquid-liquid microextraction (DLLME) is an analytical technique, based in the dispersion of extraction solvent assisted with a disperser solvent within an aqueous solution that generates a very high contact area between the aqueous phase and the extraction solvent. The present study reports the application of a DLLME-HPLC-DAD for the simultaneous separation and determination of four paraben preservatives (methyl-, ethyl-, propyl-, and n-butyl-paraben) in surface water. The surface water samples were collected during the four seasons of a year period (december 13, february 14, may 14, and august 14), from Mogi river, in São Paulo state, Brazil. The DLLME-HPLC with diode array detection method shows a good chromatographic separation for the 4 parabens studied (methyl-, ethyl-, propyl-, and n-butyl). The method exhibit detection limits from  $1.0\mu\text{g L}^{-1}$  for methylparaben,  $1.0\mu\text{g L}^{-1}$  for ethylparaben (EP),  $0.8\mu\text{g L}^{-1}$  propylparaben (PP), and  $1.0\mu\text{g L}^{-1}$  butylparaben (BP). Good recovery index for the extraction procedure, from 30.3% (MP) to 68.0% (PP), and good reproducibility ( $> 95\%$  RSD). Surface water samples collected from Mogi River, showed the average levels of parabens ranging from:  $< 1.00\mu\text{g L}^{-1}$  (EP) to  $21.83\mu\text{g L}^{-1}$  (MP) during spring season,  $1.10\mu\text{g L}^{-1}$  (PP) to  $27.50\mu\text{g L}^{-1}$  (MP) during summer,  $1.64\mu\text{g L}^{-1}$  (BP) to  $4.80\mu\text{g L}^{-1}$  (MP) autumn, and  $0.88\mu\text{g L}^{-1}$  (MP) to  $6.76\mu\text{g L}^{-1}$  (MP) during winter. Probably these levels are associated with the greatest number of people, residences, and industries located in the river region, which has a higher consumption of products containing preservatives (food, personal care products, pharmaceuticals hygiene, and others). **Acknowledgment:** This work was supported by CNPq (150540/2013-2).

## WE172

### Screening and Quantitation of Targeted and Non-targeted Environmental Pollutants in Water Samples

J. Stahl-Zeng, AB SCIEX; D. McMillan, Sciex; A. Sage, ABSCIEX / marketing Pharmaceuticals and Personal Care Products (PPCP) are environmental contaminants of growing concern. In order to properly assess the effects of such compounds on our environment, especially their disruption of endocrine function in mammals and fish, it is necessary to accurately monitor their presence in the environment. The diversity of chemical properties of these compounds makes method development challenging. Here we present results of PPCP findings in water samples collected in different geographies and from different type of water, including drinking water, creeks, rivers, lakes, sea etc. All samples were analyzed by direct injection Liquid Chromatography coupled to tandem Mass Spectrometry (LC/MS/MS). Two analytical methods were used. A method which enables the quantitation of PPCP at low ppt levels using Multiple Reaction Monitoring (MRM) and their identification using full scan MS/MS with mass spectral library searching using a hybrid triple quadrupole linear ion trap LC-MS/MS system (QTRAP® 6500). In addition a high resolution and accurate mass LC/MS/MS system (TripleTOF™ 5600+) was used to further explore collected samples for unexpected analytes. Data processing turned out to be the bottleneck of the general unknown screening methodology. New and advanced data processing tools were used to automatically identify unexpected and unknown pollutants. Key words: unknown screening, PPCP in water, quantitation, identification

### New molecularly imprinted polymers (MIP) used as SPE clean up method and as a passive sampler receiving phase for the catchment of glyphosate and AMPA in water

C. Berho, BRGM / Laboratory Division; B. Claude, Université Orléans / ICOA UMR; L. Amalric, BRGM; a. togola, BRGM / Laboratory Division; E. Grellet, BRGM; S. Bayoudh, POLYINTELL; K. Puzio, P. Morin, Université Orléans / ICOA UMR

Glyphosate is a broad-spectrum systemic herbicide which is widely used in the world. As very polar molecules, glyphosate and its main degradation product AMPA are difficult to extract with organic solvents and common solid phase extraction (SPE) sorbents. A new SPE sorbent based on Molecularly Imprinted Polymers (MIP) was thus developed for Glyphosate and AMPA. The performance of the MIP is evaluated by the comparison between the classical method for the quantification of glyphosate and AMPA in water samples (on line SPE/UPLC/MS/MS after derivatization) with those obtained after MIP-SPE clean method followed with classical method. Results have shown that the MIP as a SPE clean up method allows the catchment both molecules in real water matrices which present different physico-chemical properties. The influence of metals concentration in samples on the recovery rates was also studied as metals are likely to form complexes with glyphosate in natural waters. This sorbent was also tested as an integrative passive sampler (POCIS) receiving phase since the classical version of POCIS with OASIS HLB receiving phase cannot catch these molecules of interest. The calibration of POCIS-MIP in laboratory conditions has led to laboratory sampling rates estimation for AMPA and glyphosate which are necessary for future field application of POCIS-MIP. We acknowledge financial support from French National Research Agency (ANR ECOTECH 2011 ORIGAMI project 11 ECOT 003) Key words : molecular imprinted polymers, passive sampling, POCIS, AMPA, glyphosate

## WE174

### Fast and sensitive analysis of drug residues in water using on line SPE-UHPLC-MS/MS with ultra fast polarity switching

M. LEVI, SHIMADZU France / Applications; S. MOREAU, Shimadzu Europa GmbH

As monitoring of drug residue in drinking and surface water is becoming of major concern in western countries, the environmental laboratories must face the increase in analysis request as well as the increase in the number of compound to be screened. In parallel, as long as no consensus as been found on regulatory reporting levels, the assay sensitivity must be very high to not miss any compound. Thus, laboratories need a simple, rapid, reliable, sensitive and cost effective method to screen and accurately quantitate drug residues in a variety of water samples. A method was then set up to fulfill these requirements. On line SPE is a useful tool to enable large sample volume injections. But due to the chemical diversity of target compounds, sample clean up can not be pushed too far to not lose polar compounds. Then matrix effect or ion suppression can be problematic for accurate quantification. Then, a very sensitive Mass Spectrometer as well as very efficient chromatography were necessary to compensate the relatively low sample volume injection. The method presented is able to screen and accurately quantitate around 150 drugs or metabolites in about 10 minutes (including sample preparation). Compounds were from diverse pharmaceutical classes like NSAIDs, steroids, antibiotics, psychotropics or antidepressants. Ultra fast polarity switching was found to be essential to ensure data quality. Validation results are presented, including accuracy in several matrices, as well as a comparison with a direct injection method.

## WE175

### Development of an On-line SPE LC-MS/MS method for the analysis of antibiotics in waste- and surface water

A. Meierjohann, Abo Akademi University / Laboratory of Organic chemistry; E. Krzymyk, Abo Akademi University / Laboratory Of Organic Chemistry; L. Kronberg, Abo Akademi University

Antibiotics are one of the most important classes of pharmaceuticals having made a large number of previously often fatal bacterial infections easily curable. Because of the common use and importance of these compounds in modern medicine, the increased appearance of multi-drug resistant bacteria in recent years has caused concern. An expected hot spot for the formation and proliferation of resistance genes are wastewater treatment plants (WWTPs), where a continuous flow of sublethal concentrations of antibiotics and a large bacterial community come together. It has long been known that pharmaceuticals that have been consumed and subsequently excreted can be found in WWTPs where they are often only partially removed in the activated sludge process and then released in the recipient environmental waters. Analysis of trace amounts of organic contaminants in environmental samples is generally an expensive and time consuming work. In this work we have developed a fast and cost efficient On-line SPE LC-MS/MS method for the analysis of 18 commonly used antibiotics and metabolites, as well as the anti-epileptic drug carbamazepine, which is used as a tracer for wastewater contamination. All the compounds of interest were absorbed in the trapping column and could be detected by the mass spectrometer. The method gave linear calibration curves and excellent detection limits around 1 – 5 ng/l for all compounds. The relative standard deviation (RSD) for injections of 10 separately prepared samples at the low concentration of 5 ng/l ranged from 4 – 45 % RSD and from 2 – 32 % for the higher concentration of 100 ng/l, with most compounds under 20 % RSD at both the high and the low concentration.

## WE176

### DETERMINATION OF GLYPHOSATE AND ITS DEGRADATION PRODUCT WATER SURFACE.

O.P. Amarante Jr, IFMA / PACA; G.H. Pinheiro, A.F. Moraes, D.H. Coelho, N.M. Brito, IFMA / DAQ; T.R. Franco, UFMA

This research was designed to evaluate the contamination of surface water in the state of Maranhão, northeastern Brazil, the use of glyphosate pesticide. The herbicide, non-selective and systemic, is the compound most often employed in agriculture, chemical weed control in several municipalities in the maintenance of electricity transmission networks, in gardens, gardening and family agriculture in this state. The most widely used chromatographic method employing HPLC with post-column derivation to obtain compound with a chromophore group to be determined by fluorescence. In this study we used the ion chromatography. The analysis was performed using Dionex Ion Chromatograph ICS3000-DUAL, Thermo Scientific. Analytical conditions: Column Term Scientific IonPac AS19, 2x250 mm / AG19 2x50 mm; flow 0.35 ml min<sup>-1</sup>; 30 °C; conductivity detector ASRS-300 with self-regenerative suppression (2 mm), at 35 mA; injection volume of 50 uL with autosampler; gradient generated in situ by Thermo Scientific Sionex III EGC-KOH cartridge. Standards of glyphosate and AMPA are provided by Dr. EHRINSTORFER GmbH (Germany) certificated for analysis (HPLC) purity and exhibit 97.5 and 97% respectively. There were sufficiently resolved peaks with retention time in 13.6 min for AMPA and 21.4 min for glyphosate. It was observed that some samples were contaminated only with glyphosate, others only with AMPA. For some samples were not detected any of the studied compounds. This result suggests that the compound for the samples with the degradation product was applied for some time and, due to biodegradation processes or physical or chemical degradation, currently can only be detected secondary pollutant. Those in which the herbicide was detected, this molecule may have been used more recently or weather conditions were not favorable for its degradation. The strong tendency of glyphosate to bind to silica can be a form of withdrawal from polluting the waters

by association to particulate matter and subsequent deposition in the sediment. The proposed analytical method is efficient for the determination of compounds of interest displayed good accuracy. Recoveries were between 70 and 120% for both compounds. The samples show different realities in the state, but herbicide and its degradation products residues were found in both agricultural municipalities as in São Luís, a more urbanized and industrial city.

#### WE177

##### **The Use of Molecular Markers to Quantify Estrogens in Natural Waters by LC-MS/MS**

J. Hendricks, J.J. Harwood, Tennessee Technological University / Chemistry  
Molecular markers have been used to indicate the sources of pollutants in water. We have extended this application to use molecular markers to indicate the presence of trace pharmaceuticals and personal care products (PPCPs). Specifically, we are investigating whether the artificial sweetener sucralose might be used as a marker of the presence of estrogens (estrone, 17 $\beta$ -estradiol and 17 $\alpha$ -ethinylestradiol), and of pharmaceuticals (carbamazepine) in waters. Carbamazepine is frequently detected in water bodies. According to Paulo et al. (2012), approximately 30% is unchanged and subsequently discharged through the feces. The compound is so frequently found in wastewater treatment effluent that it has itself been suggested as a molecular marker. Sucralose is now found in wastewater, groundwater, surface water and drinking water. Due to its stability, ubiquitous occurrence and relatively high environmental concentrations, it is considered one of the most promising molecular markers of wastewater. Fortunately, these common PPCPs of concern and sucralose can all be analyzed in a single analysis by LC-MS. The compounds are separated with the common ODS stationary phase and ammonium acetate/acetonitrile/water eluent. The electrospray LC-MS interface sufficiently ionizes all the compounds for analysis. Over a six month period we tested for a correlation between the concentration of sucralose with the presence and concentrations of the estrogens and carbamazepine in the wastewater treatment influent and effluent of three cities having various populations. Grab samples were collected and analyzed at the beginning and end of three one month periods over a six month study. POCIS samplers were installed for the duration of these periods, and were extracted and analyzed for the compounds. The results of this initial study have indicated that estrogen and carbamazepine levels can be correlated to the molecular marker sucralose. We demonstrated the use of LC-MS to simultaneously analyze for all these compounds with minimal sample preparation. This approach could be extended to find correlations between sucralose concentration and other PPCP's in the aqueous environment. Finally, the analytical methods we have developed can be used by researchers investigating the impacts of PPCP's on aquatic organisms, and on drinking water sources.

##### **Assessment of trace element concentration in archaeological sites by the use of PXRF**

M. Gutiérrez Rodríguez, University of Granada / Department of Prehistory and Archaeology; F.M. Peinado, University of Granada / edafología y química agrícola; A. Morgado Rodríguez, University of Granada / Department of Prehistory and Archaeology

The necessary preservation of the archaeological heritage may involve certain drawbacks for researchers. In some cases protection impedes close-up analyses and detailed observations, and in other cases sampling is prohibited. Moreover, excavation process is a destructive technique in order to obtain historical data of the past which implies the loss of the archaeological record. In this sense, the field portable X-ray fluorescence (PXRF) analyser is a useful tool for screening and assessing archaeological soils and sediments. This equipment allows *in situ* trace-element concentrations to be determined both rapidly and easily. To check its potential applicability, 5 archaeological sites of southern Iberia dated in the V millennium have been sampled. Samples were analysed *in situ* using a field PXRF elemental spectrometer NitonXLt 792WY. The instrument is equipped with a 40 kV X-ray tube with an Ag anode target excitation source, and a Silicon PIN-diode featuring a Peltier cooled detector. The results indicated statistical significant differences between the different samples analysed for Zn and Cu, metals that are involved in the copper metallurgy. It is noteworthy that southern Iberia was a former place of development of early mining during the V millennium. PXRF results have been correlated successfully with ICP-MS and treated statistically (Tukey Test). Anomalies detected in archaeological sites show a good correlation with moments of activity and decrease episodes of human activity as well as the widespread production of metal tools at the expense of flint technology. In this study, PXRF has proved to be a useful tool for screening and assessing archaeological records for quick and easy *in situ* determination of trace-element concentrations.

##### **Rapid detection and classification of organic pollutants by Raman spectroscopy and Surface Plasmon Resonance imaging: application to wood recycling industry**

H.Q. Nguyen, Université du Maine / Institut des Molécules et Matériaux du Mans IMMM; f. lagarde, Institute of molecules and materials of Le Mans / Institute of Materials and Molecules of Le Mans IMMM UMR CNRS; P. Daniel, University of Le Mans / Institut des Molécules et Matériaux du Mans IMMM; G. Louarn,

University of Nantes / Institut des Matériaux Jean Rouxel IMN

Wood has been used as an important material of human life for thousands of years. Wood can be applied widely in both everyday life and industry as tools, construction materials and fuels. However, for applications and for longer preservation, wood has to be chemically treated with pesticides or some molecules those are known to be toxic. Two major kinds of chemical pollutants are used: heavy metals (typically are chromium copper arsenic – CCA) and organic pollutants such as polychlorinated biphenyls (PCBs), pentachlorophenol (PCP) and creosote. Wood products, at the end of their using life, are discharge and could be recycled but the presence of these toxic molecules in waste wood hinders their recycling process. Besides, the chemical molecules present in wood can be washed by rain and end up in rivers and surface waters, which is of course a strong environmental concern. Therefore, rapid detection and classification of these molecules in wood items are necessary and are a potential demand from the industries implied in wood recycling. Indeed, in France, the recycling companies are still classifying waste wood relying mostly on their sources, without any analytical procedure. Three classes are considered: A for clean wood, B for wood treated with non-hazardous material and C for the wood treated with hazardous materials. Nowadays only classes A and B can be recycled, mainly for particleboard and combustion fuel, and only heavy metals contamination is monitored by X - Fluorescence. The detection of organic pollutants lacks of a really efficient technique. In this work, two techniques were tested to detect organic pollutants in wood items: i) Raman spectroscopy which is a fast, non-destructive and non-invasive fingerprint technique for detection of organic molecules that can be used *in-situ*. Associated with chemometrics, Raman spectroscopy was used in this work to discriminate wood items by classes and monitor the presence of pollutants. ii) Surface Plasmon Resonance imaging (SPRI), an innovative technique that can provide a sensitive and real-time measurement for molecular detection, was also used for non-target detection of organic pollutant in wood recycling leachate. The advantages of both techniques for a quick detection and quantification of organic pollutants in waste wood and leachate from wood industry will be presented.

#### WE180

##### **New sensor for direct detection of pesticides in water by Raman spectroscopy coupled with enzymatic functionalized nanoparticles**

A. EL ALAMI, Institute of Materials and Molecules of Le Mans IMMM UMR CNRS; f. lagarde, Institute of molecules and materials of Le Mans / Institute of Materials and Molecules of Le Mans IMMM UMR CNRS; B. MIMOUNA, Faculté des Sciences Dhar Mehraz Fés / Laboratoire de Physique du Solide équipe polymères et nanomatériaux; P. Daniel, University of Le Mans / Institut des Molécules et Matériaux du Mans IMMM

Pesticides are worldwide used in agriculture and industries. Some of them are highly toxic and may perturb some vital functions in organisms. In this framework it is very important to dispose of tools able to detect very fast and with very high sensitivity these kinds of compounds. In this work an acetylcholinesterase (ACHE) biosensor was developed in the goal of a direct detection of pesticides in water. Our method is based on Surface Enhanced Raman Scattering (SERS) phenomenon which corresponds to the increasing of a Raman signal when an analyte is at the vicinity of a metallic rough surface. Organophosphored and carbamate pesticides are known to block the activity of ACHE, an important enzyme implied in nervous system functioning. The activity of ACHE is a sensitive indicator of the presence of pesticides and its inhibition was already used for detection purpose. Here, once immobilized via an electrochemical process, the enzyme was placed at the contact of its substrate (acetylcholine) and the enzymatic reaction (transformation of the substrate in choline and acetic acid) was monitored by Raman spectroscopy. By using dedicated gold nanoparticles, the Raman signal of the generated products was detected and enhanced giving a specific SERS spectrum, reference spectra of a "healthy" enzyme. In presence of pesticides, the enzyme is inhibited leading to the absence of enzymatic reaction and to a different Raman spectrum. In this study, paraoxon and carbaryl were used as model pesticides and the first results showed that this biosensor gave highly sensitive and very fast responses. This biosensor can be used for a non-specific and on-line detection of enzyme inhibitors.

#### WE181

##### **Analysing Personal Care Products in biota by liquid chromatography - atmospheric pressure photoionisation - mass spectrometry**

D. Molins Delgado, Environmental Chemistry; R. Muñoz-Conde, IDAEA CSIC; S. Diaz-Cruz, IDAEA-CSIC / Environmental Chemistry; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research

Personal care products (PCPs) is a generic term that describes a group of organic chemicals included in different products widely used in daily human life (such as toothpaste, shampoo, cosmetics and even in food), being used in considerable quantities. After use, they may be absorbed by the body and excreted or washed after its application. PCPs and their metabolites enter the aquatic environment and reach WWTPs [1], where they are partially eliminated [2]. On recent times, the concern about the potential hazardous risk associated to them and their byproducts [3], has been on the rise. Traditionally, the analysis of PCPs have been carried out limiting the amount of compounds to a few per analysis. Fragrances have been analysed using gas chromatography (GC), whereas UV filters and parabens transitioned to liquid chromatography (LC). Electrospray ionisation (ESI) sources, in both ionisation modes became the standard. Atmospheric pressure

photoionization (APPI) source offers a new step forward the multiclass analysis of PCPs, as was found to be useful to analyse sunscreens and fragrances from lake sediment samples in a previous study by Chiaia-Hernandez et al. [4]. In the present study we expand the applicability of APPI to analyse a selected group of PCPs in biological samples. Fish samples were extracted by pressured liquid extraction (PLE). A purification step consisting in a solid phase extraction (SPE) was carried out afterwards [5]. The samples were prepared to further analysis with high performance liquid chromatography-atmospheric pressure photoionisation-triple quadrupole (HPLC-APPI-QqQ-MS/MS). The method was validated and then its applicability was tested through the analysis of some fish samples. The performance of the method along with the levels of PCPs observed in the collected fish samples will be presented. *Acknowledgement* - The authors acknowledge the research funding from the Generalitat de Catalunya (Consolidated Research Group: Water and Soil Quality Unit 2014-SGR-418). ## WE182 DEVELOPMENT OF ANALYTICAL METHOD FOR CMIT AND MIT IN WET WIPES

J. Heo, Pusan National University / Civil and Environmental Engineering; U. Kim, Pusan National University / Department of Civil and Environmental Engineering; J. Oh, Pusan National University

In 2012, the humidifier disinfectant had become a serious social problem in Korea due to the 78 deaths including the infants caused by the misuse of humidifier disinfectants. Among the many humidifier disinfectants, the CMIT (chloromethylisothiazolion) and MIT (methylisothiazolione) are the representative chemicals and widely used in products like the liquid type of cleaner, washing materials and shampoo etc. They were known to cause skin irritation and contact allergens (Fewings J. and Menné T. et al., 1999) as well as inhalation toxicity (EPA738-R-98-012., 1998). Even though their frequent use in living environment, limited studies on the toxic effect on human or the occurrence of these chemicals in environment were performed. Therefore, in this study we aimed to develop analytical method for CMIT and MIT in wet wipes which are frequently used for infants, using the Liquid chromatography/Mass spectrometry. In order to set up the efficient pretreatment method, ultrasonic associated extraction (UAE) method and direct injection method were tested using the liquid fraction of commercial wet wipes). For evaluation of extraction efficiency, 1000 ng of CMIT and MIT and internal standard (Atrazine-d<sub>5</sub> and OIT-d<sub>17</sub>) were spiked in wet wipes liquid samples. The extraction efficiency of CMIT and MIT for UAE method was 77~102% and 87~110%, respectively, and the extraction efficiency of CMIT and MIT for direct injection method was 50~170% and 19~50%, respectively. The internal standard average recoveries of direct injection and UAE method were 54% and 72%, respectively. Consequently, UAE method was chosen for wet wipes pretreatment method in this study. For validation of this method, accuracy and precision were obtained from the experiment of seven replicate wet wipe samples spiked 1 ng of CMIT and MIT, and those accuracy (precision) of CMIT and MIT were 98.6 (4.1%) and 118.9 (3.1%), respectively. Method detection limits (MDLs) was calculated by multiplying three times of standard deviations of seven samples, and the MDLs for CMIT and MIT were 0.013 and 0.011 mg/kg, respectively. Those MDL values were quite lower than the previously reported analytical methods using LC-UV/DAD (e.g., CMIT; 15 mg/kg, MIT; 5 mg/kg) (KATS, 2012) Keywords: CMIT/MIT, wet wipes, UAE, LC/MS *Acknowledgement* – This work was funded by a grant from the Korean Ministry of Environment (MOE) through “The Environment Health Action Program (2012001370008)”

## WE183 Microbial fingerprinting of an improved strategy to assess chemical persistence at the water-sediment interface

C. Islas, Fraunhofer IME / Environmental and Food Analysis; C. Diaz, Fraunhofer IME; P. Shrestha, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; D. Hennecke, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology / Ecological chemistry

The degradability of chemicals in different environmental compartments is one of the major determinants of their environmental fate and therefore plays a crucial role in regulatory decision making. In the study of chemicals degradability, simulation tests present several uncertainties with regard to performance, evaluation and data interpretation. In this context, this work aimed to evaluate the microbial population in four simulation tests to see how influences the degradability of four well studied substances. Two natural sediments, with different textures, were selected to simulate the biodegradation of different test substances (Aniline, Pyriproxyfen, Voriconazol, Celecoxib). For every sediment/test substance, four tests were conducted in parallel including: a setting according OECD 308, OECD 308 modified (with a thinner, ideally fully aerobic sediment layer), OECD 309 and OECD 309 modified (with higher sediment content). The microbial diversity of the different settings was studied with polymerase chain reaction-denaturing gradient gel electrophoresis (PCR-DGGE). Eubacterial primers were used, in both, qRT-PCR and DGGE (GC clamped primers). Additionally, specific primers

targeting important functional groups of bacteria were used. Preliminary results of the RNA extractions from the coarse sediment (low OC) showed 4 times less concentration of RNA per gram of sediment than the fine sediment (high OC), suggesting less microbial activity, however this is not necessarily translated in less biodegradability. The DGGE analysis will indicate shifting and diversity of the microbial population which might explain the biodegradation results better than a total estimation of the active microbial population. Studies are not yet finished but it can be concluded already that a deeper analysis of microbial diversity is needed and further studies to evaluate in depth the differences observed.

## WE184 PTR-ToF-MS as novel tool for real-time tracking nanopalladium(0)-catalyzed transformation reactions of persistent organohalogen compounds

F.C. Fischer, University Giessen / Institute of Soil Science and Soil Conservation; L. Böhm, Justus Liebig University Giessen / Institute of Soil Science and Soil Conservation Research Centre for BioSystems Land Use and Nutrition IFZ; M. Müller, University of Innsbruck / Institute for Ion Physics and Applied Physics; F. Schmidt, Institut für Environmental Research; M. Schlüter, Justus Liebig University Giessen / Institute of Applied Microbiology Research Centre for BioSystems Land Use and Nutrition IFZ; F. Axt, Justus Liebig University Giessen / Institute of Soil Science and Soil Conservation Research Centre for BioSystems Land Use and Nutrition IFZ; A. Wisthaler, University of Innsbruck / Institute for Ion Physics and Applied Physics; M. Bunge, Justus Liebig University Giessen / Institute of Applied Microbiology; R. Düring, Justus Liebig University Giessen / Institute of Soil Science and Soil Conservation Research Centre for BioSystems Land Use and Nutrition IFZ

The ability of palladium(0) nanocatalysts for the transformation and potential detoxification of persistent organic pollutants has been demonstrated in previous studies. Novel Pd(0) nanocatalysts, synthesized by controlled coalescence (D90: 63 nm), have shown a rapid dechlorination of hexachlorobenzene (HCB). The high HCB ( $C_{HCB} = 3 \mu\text{g L}^{-1}$ ) dechlorination rate of  $A_{Pd,HCB} = 204 \text{ L g}^{-1} \text{ min}^{-1}$  complicates data acquisition by conventional off-line analysis such as GC-MS to follow dehalogenation pathways, reaction kinetics and nanocatalyst activity.

PTR-ToF-MS is a state-of-the-art technique for on-line and real-time monitoring of volatile organic compounds (VOCs) without sample preparation, solvent extraction and clean-up steps. Due to its high mass resolving power of  $> 4000 \text{ M}/\Delta\text{M}$ , a limit of detection below 5 pptV and a sensitivity of more than 120 cps/ppbV (e.g., benzene), it is increasingly applied in environmental analysis. For the present experimental setup, nanoPd(0)-catalyzed dehalogenation of HCB and of some potential dehalogenation intermediates was tested in separate experiments. The compounds were dissolved in ultra-pure water in airtight flasks and continuously purged with  $\text{N}_2/\text{H}_2$  (98%/2%). After equilibrium of the parent compounds, the hydrogen-activated aqueous Pd(0) nanoparticle suspensions were injected. The headspace of the samples was continuously analyzed by PTR-ToF-MS at a time resolution of 10 s, using  $\text{H}_3\text{O}^+$  or  $\text{O}_2^+$  as primary reactants. Exemplarily, the dehalogenation of a saturated HCB solution in the presence of 192 ppb Pd(0) nanocatalysts resulted in the immediate formation of 28 ppbV benzene, but depending on nanocatalyst types and concentrations, different dehalogenation products and altered dehalogenation rates were observed. To assess the stability of the nanocatalysts and to estimate their durability under environmental conditions, the approach was extended to experiments using different nanoparticle fractions, synthesis routes (including laser ablation and microbial “bioPalladium” synthesis), directed catalyst poisoning using reduced sulfur compounds, and oxidative catalyst inactivation. Further tests with “old” and emerging persistent organic pollutants are under way and will demonstrate the high potential of Pd(0) nanocatalysts for clean-up of drinking water, aquifers and specific municipal and industrial effluents, as well as the suitability of PTR-ToF-MS to assess the pertinent transformation and detoxification reactions. \n

## WE185 Triclosan transformation products: Environmental risk evaluation

M.J. Bock, T.R. Barber, P.C. Fuchsman, ENVIRON International Corp.; M. Capdevielle, Colgate-Palmolive Company

The use of personal care products has led to an increase in the numbers and quantities of chemicals discharged to domestic wastewater. A variety of abiotic chemical transformations may occur during wastewater treatment, and the creation of different chemical species during treatment and post discharge can present additional challenges in assessing environmental impacts. Triclosan is a broad-spectrum antibacterial compound that is widely used in a variety of clinical settings and consumer products. The primary disposal pathway for triclosan is down-the-drain disposal, followed by wastewater treatment. Greater than 95% of the triclosan in wastewater is removed by a typical wastewater treatment plant, with residual quantities released in the effluent. Transformation products formed during treatment may also be released. We reviewed potential abiotic triclosan transformation pathways and products, compiled environmental exposure data, and evaluated the toxicological significance to aquatic organisms. Mechanisms for generating transformation products include UV irradiance/photolysis and chlorination. Theoretically, these processes may produce a variety of intermediate products, such as certain chlorinated triclosan derivatives and certain dioxins. However, the triclosan transformation products are not related to the dioxin congeners substituted in the 2,3,7,8 positions and do not show “dioxin-like”

toxicity. In fact, the triclosan-derived dioxin congeners are rapidly metabolized and do not bioaccumulate in fish, so the potential risk to mammals, birds, and fish is minimal. Thus, although they share the name “dioxin” with certain highly toxic compounds, the dioxin congeners derived from triclosan are not of significant environmental concern.

#### WE186

##### **Monitoring of Benzene, Toluene, Ethylbenzene and Xylene (BTEX) Residues in Arable Lands around Oil Reservoir**

B. Park, RDA / Chemical Safety; S. Lim, J. Kim, G. Choi, NAAS RDA

The benzene, toluene, ethylbenzene and xylene (BTEX), which are volatile aromatic hydrocarbons and main constituents of gasoline, are neuro-carcinogenic organic pollutants in soil and groundwater. Korea Ministry of Environment has established the maximum permissible level of BTEX in arable soil to 1, 20, 50 and 15 mg kg<sup>-1</sup>, respectively. To understand an arable soil contamination by BTEX, we collected 92 samples from the arable lands around oil reservoir, and analyzed the BTEX residue using a GS-MS with head-space sampler. A linear correlation between BTEX concentration and peak areas was detected with coefficient correlations in the range of 0.9807-0.9995. The method LOQ of BTEX was 0.002, 0.014, 0.084, and 0.038 mg kg<sup>-1</sup>, respectively. Recoveries of 0.5 mg kg<sup>-1</sup> BTEX were found to be 73.7-96.9%. The precision was reliable since RSD percentage (0.7-7.5%) was below 30, which was the normal percent value. Also, BTEX in all samples were detected under the LOQ. These results showed that the investigated arable soils around airport and oil reservoir in Korea were not contaminated by oils.

#### WE187

##### **A Design of Experiment Approach for Optimizing LC-HR/MS Data Acquisition and Processing on Environmental Contaminants**

M. Hu, The Helmholtz Centre for Environmental Research - UFZ RWTH Aachen University / EffectDirected Analysis; M. Krauss, W. Brack, T. Schulze, Helmholtz centre for environmental research - UFZ / EffectDirected Analysis

Liquid chromatography-high resolution mass spectrometry (LC-HRMS) is a technique commonly applied in multi- and non-target screening of environmental contaminants. Evaluation of LC-HRMS screening data typically involves peak picking software. The performance of this kind of software and thus the number of identified peaks may depend very much on parameter settings but also on sample preparation and chemical analysis itself. However, the performance of such software has not been widely assessed so far. Therefore, sample preparation, LC-HRMS analysis and peak picking with MZmine 2 software was rigorously evaluated using water extracts spiked with a known set of environmental contaminants at environmentally relevant concentrations. To this end, a strategy for optimizing data acquisition and processing parameters with a two-step Design of Experiment (DoE) approach is proposed: (i) D-optimal design was applied for optimizing parameter setup of sample preparation and LC-HR/MS analysis (reverse phase LC on a C18 column, coupled to a LTQ Orbitrap XL instrument); (ii) Central Component Face (CCF) design was used to generate different combinations of parameter settings for MZmine 2. The optimized procedure was applied on water samples from Saale catchment in Germany. The results indicate that data acquisition parameters play key roles for data processing. For example, a reduction of cycling time of Orbitrap MS within a reasonable domain significantly increased the number of peaks that could be deconvoluted by MZmine 2. Since lower cycling time improves peak shape, more peaks fulfill the criteria of deconvolution parameter in MZmine 2. Furthermore, the optimal setting of the MZmine 2 parameters increased the number of peaks identified by 20% compared to the worst setting. The DoE approach was found to be very useful for optimizing data evaluation data evaluation processes which involve parameters tuning. We demonstrate that MZmine 2 under optimal parameter settings can significantly enhance the throughput of analysis and detect more than 75% of the peaks that can be manually identified both in spiked and native surface water samples.

#### WE188

##### **Combining Equilibrium Sampling with Non-Target Analysis of Hydrophobic Complex Mixtures in a Complex Matrix**

K. Knudsmark Jessing, University of Copenhagen / Department of Plant and Environmental Sciences; J.H. Christensen, University of Copenhagen; P. Mayer, Technical University of Denmark / Department of Environmental Engineering

Risk assessment of complex mixtures is a serious challenge. It is most often based on one-target chemical analysis and one-compound toxicity tests of priority pollutants. However, this approach is meaningless if key contaminants are not known beforehand or the measured compounds do not exert the observed toxicity. Additionally, such chemical analysis is typically based on exhaustive extractions yielding total pollutant concentrations that do not reflect the actual contaminant exposure of organisms. In this study we combine two novel strategies to 1) enrich hydrophobic compounds so that the obtained extracts reflect the available exposure in the matrix and 2) obtain non-targeted chemical fingerprints of these extracts. Sewage sludge is the studied matrix. In 1) equilibrium sampling is performed with jars coated on the inside with micrometer thin silicone PDMS. This polymer is chosen as it provides enrichment for hydrophobic compounds with biological relevant hydrophobicity. When equilibrium partitioning between sludge and PDMS is reached, hydrophobic compounds in the PDMS are back-extracted. This technique provides some unique features for the subsequent instrumental analysis:

the compounds are enriched by orders of magnitude in the polymer; typical interferences such as humic acids are excluded, and clean up steps largely omitted. In 2) non-targeted fingerprint analysis of the chemical activity in these extracts are then performed using comprehensive multidimensional gas-chromatography quadrupole-time-of-flight with electron and negative chemical ionization (GC × GC-QTOF-EI/NCI), providing high peak capacity and excellent separation. This novel instrumentation also provides the possibility of identification of compound groups in the sewage sludge. Data processing is performed using peak deconvolution algorithms together with pixel-based analysis. The processed data is analyzed with principal component analysis (PCA) to characterize the chemical composition of the sludge samples and determine the main relative differences in the hydrophobic chemical fingerprints. The results presented are supported by total extractions and provide new insight of chemical activity and composition of complex mixtures in complex matrices – the first step towards better risk assessments.

#### WE189

##### **Analytical and statistical approaches to preselect relevant organic compounds in the non-target screening by coupling passive sampling and high resolution spectrometry: application to groundwater**

C. SOULIER, Université Bordeaux 1 / Laboratory Division; C. Berho, a. togola, BRGM / Laboratory Division

One of ongoing challenge is to protect and preserve water resources. This involves an increased monitoring and the characterization of micropollutants, emerging substances and their metabolites or transformation products. Emerging compounds are mostly released by wastewaters discharge into surface waters and then into other environmental compartment. All these compounds are present in complex mixture at low concentration, implying the need of specific analytical methodology to identify them. The aim is to support public policy development of highlighting and identifying compounds of interest present in groundwater. The main difficulties for the implementation of monitoring are low concentration levels and mix of pollutants from various sources. No therefore there is a strong interest to combine passive sampling and high resolution mass spectrometry (HRMS). On the one hand passive sampling tools allow accumulating compounds during exposure and improving the sensitivity by their integration abilities. The Polar Organic Chemical Integrative Sampler (POCIS) were used to sampling polar and semi-polar compounds. On the other hand HRMS allows detecting and identifying organic compounds. The high resolving power, mass accuracy and the sensitive full spectrum acquisition of this technique are the key points for organic compounds screening. Different groundwater impacted by agricultural, urban or rural pressures were investigated and sampled during several months. Grab and passive sampling were deployed and analyzed by LC-QToF. To process data different approaches were investigated. The first approach is based on research from compounds listed on homemade database (around 450 with experimental data on our system as retention time, exact masses for molecular and fragment ions). The non-targeted screening was applied using statistical tools such as principal components analysis (PCA) with direct connections between original chromatograms and ion intensity. Trend plots are used to preselect relevant compounds for their identification. This approach allows making comparison of samples and giving multidimensional visualization of chemical patterns as molecular fingerprint and highlighting recurrent or specific peaks of each site. The identification of relevant signal was partially succeeded by using different database such as Norman Mass Bank or Chempidder. The workflow used allows identifying compounds never revealed in these sampling sites.

#### WE190

##### **FAST AND COMPREHENSIVE ANALYSIS OF PESTICIDES IN SURFACE WATERS BY UHPLC-HIGH RESOLUTION & HIGH MASS ACCURACY HYBRID LINEAR ION- TRAP- ORBITRAP MASS SPECTROMETRY**

C. Nannou, V. Boti, C. Tsoutsis, University of Ioannina / Department of Chemistry; N. Mantzos, TEI of Epirus / Department of Agricultural Technology; I. Konstantinou, University of Patras / Department of Environmental Natural Resources Management; G. Patakioutas, G. Karras, TEI of Epirus / Department of Agricultural Technology; T. Albanis, University of Ioannina / Department of Chemistry

The widespread use of pesticides for agricultural and non-agricultural purposes has resulted in the presence of their residues in various environmental matrices. Pesticide contamination of surface waters has been well-documented worldwide and constitutes a major issue that gives rise to concerns on a local, regional, national and global scale. Pesticide residues reach surface water mainly through agricultural run-off. Both parent pesticides and metabolites may exert a toxic action in organisms of freshwater systems, whenever the concentration of a compound is sufficient to trigger such effect. Hence, the analysis of pesticide residues in a variety of environmental matrices is necessary to ensure their safety and quality about health standards [1]. In that direction, the use of high-resolution mass spectrometers (LC-HRMS), and especially Orbitrap technologies, enables the acquisition of a theoretically unlimited number of species by means of accurate mass measurements in full-scan mode. This allows obtaining the elemental composition of acquired ions, useful for identification of targeted and untargeted compounds, metabolites, or transformation products [2]. The Orbitrap mass analyzer was first described in

2000 [3] and has now reached the status of a mainstream mass spectrometry technique. In this study, the analysis of a variety of pesticide residues by means of high mass accuracy hybrid linear ion trap-Orbitrap mass spectrometer (LTQ-Orbitrap-MS) is investigated. The identification of the positive findings is accomplished with the data from accurate masses of the target ions, based on the full-scan exact mass measurement of  $[M+H]^+$  ions, along with retention time data and characteristic on-source fragment ions. The above-mentioned procedure was evaluated in order to be applied for the estimation of the pollutant load and its seasonal distribution in natural waters of the Prefecture of Epirus (Arachthos and Louros rivers, Amvrakikos gulf), N.W. Greece. The results obtained confirm that high-resolution mass spectrometry is a helpful and reliable tool for the identification and quantitation of pesticide residues, providing at the same time high accuracy. **ACKNOWLEDGEMENTS** The research is implemented through the Operational Program "Education and Lifelong Learning" and is co-financed by the European Union (European Social Fund) and Greek national funds.

## WE191

### Development of a multiresidue method for the analysis of novel flame retardants in environmental samples using gas chromatography coupled to Time-of-Flight Mass Spectrometry

M. Lauzent, LPTC-EPOC, University of Bordeaux / UMR EPOC LPTC; P. Labadie, University of Bordeaux / UMR EPOC Equipe LPTC; K. Lemenach, University of Bordeaux / UMR CNRS EPOCLPTC; E. Geneste, Université de Bordeaux / UMR EPOC LPTC; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC

As a consequence of the phasing out or the voluntary removal of polybrominated diphenyl ether (PBDE) commercial formulations, an increasing number of alternate flame retardants are being used. In the present study, a multiresidue method based on gas chromatography coupled to Time-of-Flight (GC-ToF) mass spectrometry was developed for the determination in environmental samples of 11 alternate brominated flame retardants: (bis(2-ethyl-1-hexyl)tetrabromophthalate (BEHTBP), 2-ethylhexyl 2,3,4,5-tetrabromobenzoate (EHTBB), tetrabromoethylcyclohexane (abTBCH), octabromotrimethylphenylindane (OBIND), pentabromotoluene (PBT), pentabromoethylbenzene (PBEb), 1,2-bis(2,4,6-tribromophenoxy)ethane (BTBPE), decabromodiphenylethane (DBDPE), hexachlorocyclopentenyl-dibromocyclooctane (HCBDCO), hexabromobenzene (HBB), 2,3-dibromopropyl-2,4,6-tribromophenyl ether (DPTE)), 3 organophosphorus flame retardants (tris(2-chloroethyl) phosphate (TCEP), tris(chloropropyl)phosphate (TCPP), 1,3-Dichloro-2-propanol phosphate (TDCPP)) and 6 dechloranes and related chemicals (Dechlorane Plus (anti, syn), dechlorinated DP products (aC110DP and aC111DP), dechloranes (Dec-602 and Dec-603)). The performance of GC-ToF-based methods were compared and the system was operated either in full-scan mode (GC-ToF MS) or in tandem MS mode (GC-Q-ToF-MS). The sensitivity and selectivity of the system were assessed using both electron ionisation (EI) and electron capture negative chemical ionisation (ECNI). The capabilities of hot and cold splitless were also evaluated and method was fully validated. We will illustrate the applicability and the performances of the method with an application on the determination of alternate flame retardants in a variety of environmental samples such as fish tissues or sediments collected in French estuarine and riverine ecosystems.

## WE192

### Tidal Effects on the Occurrence of Pharmaceuticals in the River Thames using Semi-Targeted Liquid Chromatography-High Resolution Mass Spectrometry and in silico Data-Mining Tools

K. Munro, Analytical and Environmental Science; A. Edge, C.P. Martins, Thermo Fisher Scientific; D.A. Cowan, Kings College London / Drug Control Centre; L. Barron, Kings College London / Analytical and Environmental Science

The Thames Tideway runs through the heart of London. This section of the River Thames is subjected to the discharge of untreated wastewater from combined sewer overflow (CSO) vents, which form part of a Victorian sewage system that is struggling to cope with the demands of this modern day capital city. In order to flexibly assess the breadth of pharmaceutical contamination in the Tideway it is necessary to move away from traditional targeted analytical methods. Using high resolution mass spectrometry (HRMS) and *in silico* data-mining/prediction tools, it is possible to combine the traditional targeted approach with a novel non-target approach; i.e. 'semi-targeted' analysis. The use of artificial neural networks (ANNs) for the prediction of chromatographic retention time in combination with HRMS screening software holds potential to simplify the challenging identification process. Presented herein is the application of this approach to assess the effect the river tide had on the occurrence of pharmaceutical concentrations and occurrence within the Thames Tideway over a 12-hour period, and for the first time, the use of predicted retention times to potentially identify the presence of new contaminants in the River Thames. A number of structurally diverse model species were used to develop a broad targeted quantitative analytical method. The use of HRMS permitted simultaneous target analyte quantification and qualitative semi-targeted

analysis of analyte content. An optimised automated data-mining method was used to shortlist potential additional contaminants. An optimised proportion of chromatographic retention times for > 80 compounds spiked into river water were used to train, verify and blind test ANN suitability for retention time prediction in matrix. Results presented show that pharmaceutical concentration fluctuations were compound specific, with some compounds (carbamazepine) showing increasing concentrations in correlation to an increase in tide level, while others (bezafibrate) remained constant throughout the sampled time period. The use of *in silico* tools resulted in several unknown species being shortlisted and identified, with a selection later confirmed with a reference standard. Overall, the potential of semi-targeted screening has been highlighted, allowing simultaneous identification of unknowns while allowing traditional targeted quantification, enhancing the analysis of the aqueous environment.

### Characterization of influent and effluent wastewaters by high-resolution mass spectrometry: Understanding the composition of recalcitrant chemicals

N.V. Heuett, Florida International University / Department of Chemistry and Biochemistry; P.R. Gardinali, Florida International University / Chemistry Biochemistry and SERC

In order to fulfill human "needs" in our rapidly changing society, a great variety of products ranging from pharmaceuticals and personal care products (PPCPs), antibiotics, drugs of abuse (illicit and prescription), artificial sweeteners, nanomaterials, disinfection byproducts, sunscreens, pesticides, to name a few; are being manufactured, consumed, used, and disposed of, on a daily basis in households and industrial settings. This massive collection of compounds (in their unchanged form or as transformation products) is not only able to reach aquatic environments, but in some cases persist and potentially inflict detrimental effects upon it. In South Florida, wastewater treatment plants provide typical secondary treatment, followed by disinfection, and release through, oceanic outfalls, deep well injection, and/or irrigation. In many cases this type of treatment is not sufficient enough to remove all compounds, turning into a relentless source of contamination. To better understand compound diversity of wastewater, it is essential to take advantage of high-resolution instruments such as the Orbitrap, which provide great sensitivity, optimal resolution, and high accuracy. An initial assessment was performed using a reclaimed water sample (20-liter). Extraction of three 4-liter subsamples using basic liquid-liquid extraction techniques at three different pH's (3.5, 7.0, and 9.6) was carried out; and extracts were then fortified with a set of 24 isotopically label standards for quantitation purposes. A combination of target and non-target screening was performed on the extracts using LC-ESI-HRMS in both positive and negative mode. A QExactive Hybrid Quadrupole-Orbitrap HRMS was used in full scan mode at 140,000 RP for molecular characterization. Preliminary results provide a clear indication that a simple extraction process is capable of generating molecular information of complex mixtures like treated wastewater. The complexity of the spectra and the number of elemental compositions detected are related to both the extraction pH and the ionization technique. Kendrick, DBE vs. carbon number, and van Krevelen diagrams were used to identify compound families with elemental compositions containing heteroatoms like sulfur, oxygen, nitrogen, chlorine, and fluoride.

## WE194

### Detection of Designer Drugs and Relevant Metabolites in Wastewater Samples Using High Resolution Mass Spectrometry: a connection between target, suspect and unknown-unknowns.

M. Pruy, Florida International University FIU / Department of Chemistry and Biochemistry; P.R. Gardinali, Florida International University / Chemistry Biochemistry and SERC

New designer drugs are emerging in the illicit drug market faster than they could be detected or managed. Due to minor modifications made to the parent compound and the multiple options when transforming a common chemical backbone large number of novel compounds are introduced to the consumers regularly mainly driven by public perception and underground marketing. Known designer drugs can be detected as target compounds once enough evidence on their use is gathered. Novel homologues may also be detected using known fragmentation patterns of the common structural backbone or by systematic unknown-unknown workflows relying on high resolution mass spectrometry coupled to *in-silico* predictions and statistical interpretations. The aim of this study was to detect all known designer drugs, their potential metabolites and transformation products and potentially related structures in wastewater streams from influents to effluents. Wastewater samples were collected and stored in the dark at -20°C to prevent degradation. Sample treatment consisted in filtration, amendment with labeled internal standards and pre-concentration using offline or online SPE. High resolution mass spectrometry was conducted using the QExactive Orbitrap at resolutions above 70,000 with a HESI II ionization source operated in both positive and negative mode. The raw data was analyzed using a basic screening method in TraceFinder EFS using an in-house database of designer drugs previously described in the available literature. The vast majority of these compounds have never been reported in environmental samples. Chromatographic peak shapes, isotope ratios, S/N limits and retention times were used to conduct the initial screening. Preliminary assessment of archived samples yielded multiple designer drugs candidates, such as 4'-methyl- $\alpha$ -pyrrolidinohexanophenone (MHPH),

2-[4-(Ethylsulfanyl)-2,5-dimethoxyphenyl]ethanamine (2C-T-2; Rosy), 4-Methyl-5-phenyl-4,5-dihydro-1,3-oxazol-2-amine (4-MAR) and 1-(4-Methoxyphenyl)-2-propanamine (PMA). Confirmation of these compounds will be conducted using target MS/MS and available standards.

#### WE195

##### Identification of Aromatic Amines by Diagnostic Derivatization in Industrial Wastewater

m. muz, UFZ - Helmholtz Centre for Environmental Research / Effect Directed Analysis; C. Hug, Helmholtz Centre for Environmental Research / EffectDirected Analysis; W. Brack, M. Krauss, Helmholtz centre for environmental research - UFZ / Effect Directed Analysis  
Among micropollutants discharged into surface waters aromatic amines are considered to be an important class of compounds since some of them have been proved to be mutagenic and/or carcinogenic. In order to detect aromatic amines, a previously developed diagnostic derivatization method was applied to effluent samples collected from a wastewater treatment plant serving a large chemical industry area besides the municipality of Bitterfeld-Wolfen, Germany. Effluent samples were collected in six consecutive weeks (one per week) with Blue Rayon (BR), a passive sampler which is able to specifically adsorb polyaromatic compounds. After extraction of BR, extracts were analyzed using an ion trap-Orbitrap hybrid instrument (LTQ Orbitrap XL, Thermo Scientific) in ESI positive ion mode. For diagnostic derivatization of amines the labeling reagent NBD-F (4-fluoro-7-nitro-2,1,3-benzoxadiazole) was used due to its high reactivity and very low ionization by ESI in positive mode. Prior to LC-HRMS analysis, 10 µL of NBD-F solution (0.8 mM in ACN) was added to 30 µL of sample extract (in 70:30 MeOH/H<sub>2</sub>O (v/v)) and 2 µL of 20 mM ammonium acetate buffer (pH 5.7) were added. Vials were heated after the addition of NBD-F at 80 °C for 30 minutes. Peak lists from the Full scan HRMS spectra were obtained using the software MZmine. The peak lists of the original and derivatized extracts were aligned and peaks that appeared in the derivatized sample were considered as derivatives of amines. Derivatives were further confirmed by using the diagnostic neutral losses -34.0055 (-2 OH) and -64.0035 (-2 OH, -NO) after MS/MS fragmentation. The mass shift of 163.0018 was used to detect the precursor amines in the original extract. Identification of amines proceeds via determination of the molecular formula from accurate mass and isotope patterns and as subsequent search for candidate structures in the ChemSpider database. To narrow down the candidate lists, fragmentation prediction using MetFrag and the presence of a primary or secondary amino group are used as selection criteria. About 40 derivatives were detected and their identification is currently being processed.

#### WE196

##### IDENTIFICATION OF UNKNOWN IN REAL WASTEWATER THROUGH THE APPLICATION OF A LC-QTOF-MS BASED WORKFLOW

P. Gago Ferrero, IDAEA-CSIC / dep. of environmental chemistry; A. Bletsou, R. Aalizadeh, N.S. Thomaidis, University of Athens / Department of Chemistry  
A large number of organic contaminants and related transformation products (TPs) are present in wastewaters. Target analysis methods only allow the detection of a very small fraction of these substances, due to the inability to obtain standards for all that compounds and the ignorance of the existence of many of them. However, advances in high resolution mass spectrometry (HRMS) have opened up new windows of opportunity in the field of complex samples analysis [1]. The application of suspect screening, with suspected substances based on prior information but with no reference standard, greatly increases the list of substances that can be identified. Nevertheless, in most samples there are many peaks in the chromatogram among the most intense ones which not correspond to substances included in the target and suspect screening lists. Therefore, these substances are potentially relevant due to their high concentration and their identification is environmentally important. However, full identification of unknown compounds is often difficult and there is no guarantee of a successful outcome. The aim of this work is to show specific examples on the identification of unknown compounds in real wastewater (collected from the WWTP of Athens). Identifications were conducted using a developed integrated workflow based on liquid chromatography coupled to a quadrupole-time-of-flight mass spectrometer (LC-QToF-MS) to detect suspected and formerly unknown organic contaminants in wastewater. Relevant peaks (not present in our target and suspect lists) were selected based on the intensity and the presence of distinctive isotopic patterns (the most relevant substances with reasonable identification possibilities). For the selected peaks the most plausible molecular formula(s) were determined by applying thresholds of mass accuracy, isotopic pattern and commercial importance. After that, a deep evaluation of the MS/MS spectra was conducted, using both data bases (e.g. Mass Bank) and *in silico* fragmentation platform (as MetFusion) to find candidates. To assess the plausibility of the candidates a retention time prediction model was also applied. **Acknowledgment** This project was implemented under the Operational Program «Education and Lifelong Learning» and funded by the European Union (European Social Fund) and National Resources – ARISTEIA 624 (TREMOPOL project). **References** [1] E. Schymanski et al. Environ Sci Technol 48, 1811 (2014).

#### WE197

##### Do glucuronidated pharmaceuticals contribute to transformation products

##### formation in the aquatic system?

B. Zonja, IDAEA-CSIC / Environmental Chemistry; A. Delgado, IQAC-CSIC / RUBAM; S. Perez, IDAEA-CSIC / Environmental Chemistry; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research  
The present work gives insight into the behaviour of pharmaceutical glucuronides which are excreted from the human body and enter into the aquatic environment via WWTP. Initially, a retrospective suspect-screening method for the determination of the antidepressant lamotrigine and its metabolites in the aquatic environment suggested that lamotrigine undergoes unusual transformations. This was discovered by application of a generic solid-phase extraction (SPE) method to a wastewater and surface samples and their subsequent analysis with high resolution mass spectrometry (HRMS). Biodegradation reactors were amended with mixed liquor and fortified with lamotrigine at 50 ng/mL in order to identify the transformation products of lamotrigine and further compare with the transformation products already detected in the analysed real WWTP samples. Experimental lab-scale bioreactors at neutral pH and lamotrigine at environmentally relevant concentrations proved that lamotrigine was resistant to biodegradation with less than 20% elimination after one week. Discarding the possible TP formation from lamotrigine, its human metabolite, the lamotrigine glucuronide, was also degraded in the batch reactors. Since lamotrigine is extensively metabolized in liver, its glucuronide could be an important contributor to lamotrigine derived compounds in the environment. In these batch reactors, it was found that the glucuronide formed two transformation products which were previously detected in the real environmental water samples. The main TP was a direct biodegradation product (the reaction was an oxidation of the glucuronide conjugate). The other TP was formed from deconjugation of the hydrolysed glucuronide. The reaction preceding the deconjugation step is hydrolysis of the original glucuronide, which is exclusively governed by the abiotic pH change. Finally, in order to understand better the reactions glucuronides undergo, a selected number of various glucuronides were biodegraded as well. They are classified in three groups. The first class are N-C glucuronides (as lamotrigine-glucuronide), the second C-C glucuronides and the third class are the C-acyl glucuronides (connected to an acid). In total 11 additional glucuronides were degraded (5 N-C, 3 C-C and 3 C-acyl). Reactions of oxidation, migration and deconjugation were observed as well.

#### WE198

##### Method development for non-target screening of sewage sludge using gas chromatography coupled to high-resolution mass spectrometry (GC-HRMS)

C. Veenas, Umea University / Chemistry; P. Haglund, Department of Chemistry  
**Keywords:** Non-target screening, sewage sludge, method development, GC-HRMS  
**Abstract** More than 100,000 chemicals are present in the technosphere and 30,000 of these are considered to be so-called “every-day chemicals”. Sewage treatment plants (STPs) are used to remove nutrients, but also some metals and organic chemicals, from urban waters and create a less contaminated effluent. Consequently, STPs form a link between the technosphere and the environment. A by-product of the sewage treatment process is sewage sludge – a solid product that contains nutrients as well as pollutants. These nutrients make the sewage sludge attractive for applications as fertilizer on agricultural fields, provided that the contaminant levels are not too high. In order to be able to investigate pollutants occurring in sewage sludge an analytical method for comprehensive non-target screening is needed. Up till now there is no method existing that allows a full screening of sewage sludge for a wide variety of compounds with different properties, which is the ultimate goal of this project. The current work has aimed at developing a non-discriminating sample preparation method for gas chromatography - mass spectrometry (GC-MS) analysis. Pressurized liquid extraction (PLE) was used for extraction, with in-line and/or off-line clean-up. In the in-line approach silica gel was added to the PLE cell for simultaneous extraction and clean-up, whilst the off-line approach involved clean-up by gel permeation chromatography. Analysis was performed by GC high-resolution MS in both cases. Preliminary results indicate that the in-line clean-up can be used for analysis of established contaminants as well as new emerging contaminants.

#### WE199

##### Determination of priority and emerging target and non-target contaminants in aqueous samples by atmospheric pressure gas chromatography-time-of-flight-mass spectrometry (APGC-ToF-MS)

m. Pintado-Herrera, Universidad de Cádiz (Spain) / Department of Physical Chemistry; E. Gonzalez-Mazo, University of Cadiz / Physical Chemistry; P. Lara-Martin, University of Cadiz (Spain)  
This work presents the development, optimization and validation of a multi-residue method for the simultaneous determination of 102 contaminants, including fragrances, UV filters, repellents, endocrine disruptors, biocides, polycyclic aromatic hydrocarbons (PAHs), polychlorinated biphenyls (PCBs), and several types of pesticides in aqueous matrices. We have focused our attention on the possibilities offered by APGC-ToF-MS for the identification and quantification of target and non-target micropollutants in water samples after stir bar sorptive extraction (SBSE). APGC ionization occurs by charge transfer ( $M^+$ ) or protonation ( $M+H^+$ ), using a reagent gas (nitrogen) and lower energy than the traditional electronic impact (EI) so fragmentation of the molecular ion is lower. When compared to EI, we could observe that the latter is often a better option when

working with very stable compounds such as PAHs, which require higher ionization energies for ionization and fragmentation. On the other hand, better results were obtained using APGC for more labile compounds (i.e. fragrances). Moreover, APGC allows for a progressive fragmentation by applying different cone voltages and can be a very powerful tool to predict and confirm fragmentation patterns (especially if specific software such as Mass Fragment is available), therefore enabling the correct identification of some target analytes (i.e. macrocyclic fragrances) which were not properly determined by EI. Additionally, coupling APGC to ToF mass analyzers may improve not only the sensitivity for some compounds but also the mass resolution achieved in full scan mode by more conventional single quadrupole mass analyzers. Thus, the combination of accurate mass measurement, retention time and isotope models (comparison between original acquired mass spectrum and the theoretical isotope model) can be used as additional confirmation criteria during analysis of target (and non-target) compounds. We applied this technique to several environmental aquatic matrices (seawater, sewage effluent, river water and groundwater), determining the concentrations of 21 out of 102 analytes. OTNE, galaxolide, tonalide, benzophenone-3, triclosan, and homosalate were detected in all samples (up to 18.2  $\mu\text{g L}^{-1}$ ). Occurrence of several non-target compounds such as dibenzyl ketone (fragrance), dibutyl phthalate (plasticizer) or tributyl phosphate (flame retardant) was also confirmed.

## WE200

### Combining chemical and biological screening: a tool for identifying novel priority pollutants in complex environmental mixtures

M. Larsson, Orebro University / MTM research center Department of Science and Technology; O. Westman, Akademin för naturvetenskap och teknik; J. Hagberg, MTM Research Centre, Orebro University / Dept. of Science and Technology; M.M. Lam, RWTH University Aachen / MTM research center Department of Science and Technology; B. van Bavel, MTM Orebro University; M. Engwall, Orebro University / MTM research center Department of Science and Technology. Studies have shown that traditional monitoring methodology of using chemical analysis of a small number of pollutants to determine the degree of contamination in environment matrices, like soil, dust and sediment, usually overlooks potential contaminants present in the samples. The objective of the present study is to establish an analytical method to screen for organic pollutants in environmental matrices with the goal to identify (emerging) pollutants posing a hazard to ecosystems and human health. A combining of chemical and biological screening is used to evaluate the occurrence and aryl hydrocarbon receptor (AhR)-mediated toxic potential (cocktail effect) of PAHs and related compounds in complex environmental matrices. So far, two different matrices have been tested; samples from oil and/or PAH-contaminated soil, arable soil and urban road samples have been analysed by use of both GC-MS (SIM and full scan) and H4IIE-luc bioassay analysis. Statistical multivariate analysis will be used to categorise the samples and link GC-MS full scan spectra (>1400 markers) and H4IIE-luc bioassay results, that is, look for relationships between compound composition and AhR-mediated activity i.e., potential chemical markers for toxicity. The AhR-mediated potency of these compounds can then be tested individually in the bioassay. Risk assessment of contaminated areas would be easier and safer if adequate marker compounds were available. Analysis of these markers along with the monitoring pollutants may provide a broader picture of the contamination.

## WE201

### Non-target Time Trend Screening (NTTS) for Identification of Novel Xenobiotics in Human Blood

M. Plassmann, Department of applied environmental science; J.P. Benskin, Stockholm University / Environmental Science and Analytical Chemistry. Most methods for screening environmental contaminants target individual chemicals or chemical classes using highly specific analytical approaches. Despite their utility for low-level detection and quantification, these methods often overlook novel contaminants or transformation products which may pose a risk to humans and wildlife. Recent advances in mass spectrometry and chemometrics have led to development of 'non-targeted' screening approaches, in which samples are analysed without *a priori* knowledge of the contaminants of interest. These methods involve broad sample extraction procedures combined with gas- or liquid chromatography high resolution mass spectrometry (GC or LC-HRMS, respectively) and advanced data processing tools and mass spectral libraries. While demonstrating great potential for pre-screening water and sediment samples, the application of non-targeted screening to biological matrices is hampered by the presence of numerous endogenous substances, which are not easily differentiated from xenobiotics, and which often occur at concentrations several orders of magnitude higher than contaminants of interest. In the present work, we introduce Non-target Time Trend Screening (NTTS) as a novel tool for identification of xenobiotics in biological samples. The procedure involves liquid-liquid extraction with acetonitrile and salts ( $\text{MgSO}_4$  and  $\text{NaCl}$ ) and analysis by LC-HRMS. Following deconvolution and alignment, chromatographic features displaying an increase, decrease, or inflection point are flagged as potential xenobiotics for subsequent identification. To validate the approach, artificial time trends were created by fortifying human blood with model compounds at different concentrations. Spiking levels were designed to assess the minimum slope or inflection in data necessary to 'flag' a chromatographic feature for further analysis.

The application of this workflow to human whole blood time trend samples from the German Environmental Specimen Bank will be discussed. To our knowledge, this is the first report of time trends being applied to non-targeted screening in biological samples and represents a novel approach for identification of xenobiotics.

## WE202

### Novel one-step centrifugal sensor system for the detection of cyanobacterial toxin Microcystin-LR

J. Fitzgerald, Dublin City University / School of Chemical Sciences; I. Maguire, B. Heery, C. Nwankire, C. Murphy, J. Ducreé, R. O'Kennedy, Dublin City University; f. Regan, Dublin City University / Chemical Sciences. Globally, the most prevalent cyanobacterial toxins, in blooms from fresh and brackish waters, are the cyclic peptide toxins of the microcystin family. The need for on-site algal-toxin monitoring has become increasingly urgent due to the amplified demand for fresh-water and for safe, 'toxin-free' shellfish and fish stocks. Along with routine testing of shellfish stocks for biotoxins including microcystin, the EU also require routine monitoring for the presence of the causative algal species. Herein, we describe a novel, Lab-On-A-Disc (LOAD) platform which has been developed to assess microcystin toxin levels *in-situ*. Using recombinant antibody technology, the LOAD platform combines immunofluorescence with centrifugally driven microfluidic liquid handling to achieve a next-generation disposable device for high throughput sampling. A low-complexity, 'LED-Photodiode' based optical sensing system was tailor-made for the platform, which allows the fluorescence signal of the microcystin-specific reaction to be quantified. This system can rapidly and accurately detect the presence of microcystin in less than 15 minutes with minimum user interaction and maximum reproducibility. This method provides a low cost diagnostic alternative to the current laborious and costly methods used for toxin monitoring.

## WE203

### Braavoo: biosensors for real time monitoring of marine contaminants

J. Sanchís, IDAEA-CSIC / Water and Soil Quality Research Group; J. van der Meer, UNIL; M. Farre, IDAEA-CSIC; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research. BRAAVOO is a FP7:Ocean project which aims to develop innovative solutions for real-time in-situ measurement of high impact and difficult to measure marine contaminants. The BRAAVOO concept is based on unique integration of three types of sensing approaches: nano-immuno, bacterial, and algal biosensors. This robust multi-usage approach ensures the detection of specific priority pollutants (including BTEX, a wide range of alkanes, several polyaromatic hydrocarbons, selected marine toxins, pharmaceutical compounds, etcetera) at environmentally relevant concentrations, and general toxic effects in what will be an effective marine early warning platform. The three biosensors will be miniaturized and integrated into novel chip-based modules which will be located on board of a data buoy and an unmanned surface vessel. Both systems will be energetically autonomous for a period of several weeks while maintaining living cells, ensuring the reagents stability and collecting samples. Real-time data will be continuously monitored and sent to a permanent base where it can be processed. The system will also allow the collection and storage of large volume samples for re-analysis and confirmation. Several SPME-GC-MS/MS, SPE-UHPLC-ESI-Q-Orbitrap-HRMS methodologies have been developed for this purpose. The novel analytical methodologies and examples of their applications will be presented.

## WE204

### Photonic nanobiosensors for real time monitoring of chemical contaminants in marine environment

S. Herranz, Nanobiosensors and Bioanalytical Applications Group; J. Sanchís, IDAEA-CSIC / Water and Soil Quality Research Group; M. Farre, IDAEA-CSIC; M.P. Marco, IQAC-CSIC CIBER de Bioingeniería Biomateriales y Nanomedicina CIBER-BBN / Nanobiotechnology for Diagnostics NbD group; L.M. Lechuga, Institut Català de Nanociència i Nanotecnologia ICN2 CSIC & CIBER-BBN / Nanobiosensors Bioanalytical Applications Group. Marine environment supports a large number of different species of organisms and plays a key role in climate and weather patterns. Moreover, the ocean is one of Earth's most valuable natural resources, it is used for transportation (both travel and shipping) and it is a major location for leisure tourism. As a result of intensive exploitation there is a slow but steady degradation of the marine water quality. Therefore, actions against ocean pollution must be taken, and numerous monitoring programmes have been put in place by individual countries and international organisations. Therefore, there is a growing need of sensitive field analysis tools which allow to perform real-time on-site sample analysis. In this context, we are developing integrated photonics nano-immunosensors based on a silicon technology with a view to implement a complete lab-on-a-chip platform. In particular, the bimodal waveguide interferometer (BiMW) [1]. In the BiMW configuration, two guided modes of the same polarization interfere in a single waveguide, without the need of a reference arm: light from a coherent source is coupled into a single mode rib waveguide which is transformed into a thicker waveguide supporting two guided modes (fundamental and first order modes), that propagate until the output of the waveguide with different intensity distribution at

the core-cladding interface. As the fundamental mode is more confined than the first order mode, it is less sensitive to the upper cladding parameters and acts as an internal reference [2]. As target, the antifouling paint booster biocide Irgarol 1051 has been selected. The assay is based on a competitive inhibition format in which an irgarol-protein conjugate is covalently immobilized on the sensor surface. We have investigated several factors affecting sensor performance: conjugate nature and sensor surface biofunctionalization protocol, antibody concentration, regeneration conditions, etc. Preliminary results show limits of detection at the ng/L level. Further work is being carried out to fully characterize the analytical behaviour of the sensor and apply it to seawater samples analysis. [1] Zinoviev et al., 2011. J. Lightwave Technol. 29:1926-1930. [2] Duval et al., 2012. Lab Chip 12:1987-1994. *Acknowledgement* - This work has been funded by the 7FP (EU, BRAAVOO Grant Agreement No 614010). ICN2 acknowledges support from the Severo Ochoa Program (MINECO, Grant SEV-2013-0295).

## WE205

### Analysis of emerging marine toxins in seawater and biota by LC-ESI-Q-Orbitrap-HRMS

J. Sanchís, C. Bosch-Orea, IDAEA CSIC / Water and Soil Quality Research Group; M. Farre, IDAEA-CSIC; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research

The population decline of some marine filters, the discharge of nutrient-rich wastewater effluents in coastal areas and the systematic sea temperature rise due to global warming are anthropogenic factors that increase the frequency and severity of harmful algal blooms. These phenomena are defined by sudden surges in the population of planktonic organisms, including dinoflagellates (red tides), diatoms and cyanobacteria of different types. Harmful algal blooms produce marine toxins which are bioaccumulated in biota and suspended in particulate. This is of high environmental and health concern, for dinotoxins have been associated to mass mortality episodes of marine species including fish, turtles, birds and mammals; harmful effects to marine organisms; human intoxication, through contaminated seafood ingestion; and severe eutrophication. Given the high hazardousness of these substances and the scarce information about the frequency of algal bloom events, it is important to develop accurate and sensitive analytical methodologies which allow monitoring the concentration, distribution, transport and degradation of dinotoxins. In the present study, an extraction and analytical method has been developed for three toxins: Domoic acid, released by diatoms and responsible of amnesic shellfish poisoning (ASP); okadaic acid, released by dinoflagellates and responsible of diarrhetic shellfish poisoning (DSP); and neosaxitoxin, released by dinoflagellates and responsible of paralytic shellfish poisoning (PSP). For water samples, an extraction protocol based in filtration, sonication and solid phase extraction (HLB cartridges) was applied, while for biota (bivalvia), a simple ultrasound-assisted solid-liquid extraction was developed with excellent recoveries. Analysis was carried out by liquid chromatography coupled to high-resolution mass spectrometry (LC-ESI-Q-Orbitrap-MS) reaching limits of detection in the low ng/l order. Preliminary results of their application to real samples will be provided.

## WE206

### Supporting monitoring under the Water Framework Directive: Development of the first Certified Reference Material for Polycyclic Aromatic Hydrocarbons in surface water

I. Dosis, European Commission - Joint Research Centre / Institute for Reference Materials and Measurements IRMM Standards for Innovation and Sustainable Development SID Unit; M. Ricci, A. Oostra, European Commission - Joint Research Centre / Institute for Reference Materials and Measurements Standards for Innovation and Sustainable Development; H. Emteborg, European Commission Joint Research Centre Institute for Reference Materials and Measurements IRMM; A. Held, H. Emons, European Commission - Joint Research Centre / Institute for Reference Materials and Measurements Standards for Innovation and Sustainable Development

Since 2000 the Water Framework Directive (WFD)<sup>1</sup> is in force in the European Union (EU) for developing a pollution control strategy of all EU water bodies. Subsequently, a Daughter Directive<sup>2</sup> established a list of Priority Substances (PS) and set Environmental Quality Standards (EQS) for these pollutants. Polycyclic Aromatic Hydrocarbons (PAHs) are among the PS that Member States are expected to assess, monitor and control in EU water resources. The most recent Daughter Directive<sup>3</sup> re-evaluated EQS for some of the PS, including PAHs, enhancing the analytical challenges for the monitoring laboratories by lowering the concentration levels even more. In the context of the support provided by the European Commission to the Member States in order to implement the monitoring requirements stipulated by the legislation, the JRC develops the required tools for Quality Assurance and Quality Control, such as validated analytical methods and Certified Reference Materials (CRMs). The current project involves the development of a natural water matrix CRM, where humic acids are added to simulate organic matter, according to the requirements of the WFD. The CRM is designed for the analysis of the 8 PAHs that are regulated by the WFD: Naphthalene, Anthracene, Fluoranthene, Benzo[b]fluoranthene, Benzo[k]fluoranthene, Benzo[a]pyrene, Indeno[1,2,3-cd]pyrene and Benzo[ghi]perylene. Target concentrations in the CRM match or are as close as possible to the EQS. The final CRM consists of 3 items (natural surface water, humic acids solution, and PAHs spiking solution) to be combined at the laboratory's premises, following an

easy-to-apply reconstitution protocol. The candidate CRM has been characterised for its homogeneity and stability, with relative standard uncertainties that have been estimated to range from 1.3 to 8.4% and 1.3 to 10.9%, respectively. These uncertainties, along with the ones estimated from the on-going characterisation campaign, will comprise the combined uncertainty of the final certified values. The material is scheduled to be released to the market in the near future. *Z.Spalt is acknowledged for his invaluable contribution to the project.*

### Assessment of PLE and QuEChERS methods to determine pesticides in soils, sediments and sludges from Turia River Basin

a.m. reyes; K. Vasquez, J. Campo, University of Valencia; Y. Pico, University of Valencia / Medicine Preventive

Pesticides have played an important role in the development of the agriculture but most of them can reach the environment via runoff becoming a real environmental pollution and human health risk. In this sense, contamination of sediments with agricultural pesticides is still a problem of primary concern, because they are easily accumulative in these matrices. Consequently, there is increasing need for the development of well validated, accurate, time saving, low cost, modern, multicomponent methods. The purpose of this study is to compare two extraction techniques for 50 pesticides in sediments in order to identify a suitable extraction method for the multiresidue analysis of sediments, soils and sludges. The performance of two enhanced extraction techniques, such as pressurized liquid extraction (PLE) and QuEChERS extraction for the determination of pesticides in dry sediments was investigated using liquid chromatography tandem mass spectrometry (LC-MS/MS) in positive ionization mode with an electrospray ionization source (ESI). Separation was carried out on a Luna C18 column (150 x 2.0 mm, 3 µm) using a gradient elution profile with mobile phase consisting of water-methanol, both 10 mM ammonium formate. Both extraction techniques produced acceptable recoveries for the pesticides under study. Mean recoveries for PLE were 68, 72 and 71 % and for QuEChERS were 76, 73 and 82 % for soils, sediments and sludges respectively, and RSD were lower than 20%. QuEChERS procedure was selected because it was advantageous in terms of recoveries and additionally, it was low time consuming, easier and cheaper than PLE. Finally, it was validated, providing LOQs between 1 and 10 ng g<sup>-1</sup> dw with the exception of alachlor and metolachlor (25 ng g<sup>-1</sup> dw) for all matrices, and applied to determine pesticides in samples taken from Turia River Basin. *Acknowledgement.* This work has been supported by the Spanish Ministry of Economy and Competitiveness through the projects Consolider-Ingenio 2010 CSD2009 and CGL2011-29703-C02-02. **Keywords:** pesticides, pressurized liquid extraction, QuEChERS, monitoring

### Exploring four extraction procedures for the determination of perfluoroalkyl substances in solid abiotic environmental matrices.

M. Lorenzo, J. Campo, University of Valencia; a.m. reyes; Y. Pico, University of Valencia / Medicine Preventive

The analysis of perfluoroalkyl substances (PFASs) in soil, sediment and sludge is important for understanding the transport, accumulation and fate of these pollutants in the environment. A comparative study of four extraction methods for the determination of PFASs in soils and sediments was performed in order to select the one that provides better recoveries and higher sensitivity. The determination of PFASs (C4–C14, C16, C18 carboxylates, C4, C6–C8 and C10 sulfonates, two C8s sulfonamides and C10 native unsaturated telomere acid) was made by liquid chromatography-tandem mass spectrometry (LC-QqQ-MS/MS). The compared methods were based on extraction with (i) aqueous solution of acetic acid and methanol, (ii) methanol, (ii) digestion with sodium hydroxide (NaOH) in methanol and (iv) ion-pair extraction. The best results were obtained with methanol extraction which recovered a greater number of PFASs and provided recoveries between 69-90% in sediment and 86-93% in soil with relative standard deviations (RSDs) < 31%, and limits of quantification (LOQ) between 0.02-0.45 ng g<sup>-1</sup> in sediment and 0.01-0.59 ng g<sup>-1</sup> in soil. The selected method was successfully applied to Segura River sediments and Turia River soil samples. Likewise, the two methods with better results (methanol and aqueous solution of acetic acid and methanol) were also applied to other matrices not proved in this study, such as sewage sludge, to verify their effectiveness. This study demonstrates the presence of PFASs in the Valencian Community Rivers studied, and the problematic of sewage treatment plants where these compounds are not efficiently eliminated. *Acknowledgement* – The authors thank the Spanish Ministry of Economy and Competitiveness for the financial support through the projects Consolider-Ingenio 2010 CSD2009, and CGL2011-29703-C02-02. Julian Campo also acknowledges the VALi+d postdoctoral contract (APOSTD/2014/010) of the Generalitat Valenciana for funding. **Keywords:** soil, sediment, sludge, perfluoroalkyl substances

## WE209

### Use of GC/MS Triple Quadrupole instrumentation for Nitrosamine analysis

D. Cardona, D. Steiniger, H. Huebschmann, Thermo Fisher Scientific

“Classical” nitrosamine analysis was performed for many years by gas chromatography using a thermal energy analyzer (TEA) as detector. Today mass spectrometric methods have increasingly replaced the TEA. EPA method 521 by Munch and Bassett from 2004 provided a suitable GC-MS method based on chemical ionization (CI) using an ion trap mass spectrometer with internal ionization, in contrast to standard quadrupole or ion trap mass spectrometers using a dedicated (external) ion source design. At present current developments in GC-MS triple quadrupole technology deliver enhanced sensitivity and selectivity for small molecule mass range compounds and allow the detection of nitrosamines at very low concentration levels even in complex matrix samples. This is made possible by using a much simpler and standard approach with the regular electron impact ionization (EI) for a very straightforward method for low level nitrosamine analysis. The work completed demonstrates a GC-MS/MS method for routine detection and quantitation nitrosamine compounds. Special focus in the method development process was given to provide a fast, easy to implement routine method with the required sensitivity for monitoring nitrosamine compounds. The final method was evaluated for validation criteria including linearity, accuracy and precision. Method detection limits were determined in the 1 ppb range. Spiked and non-spiked water samples analyzed for low concentrations of target nitrosamines.

## WE210

### Exploration of suitable alternatives for GC/MS He carrier gas conservation

D. Cardona, T. Jeffers, T. Albertini, Thermo Fisher Scientific

The impact of increased price and decreased availability of helium continues to drive the need for carrier gas conservation in GC/MS. During sample introduction for volatile organic compound analysis via purge and trap apparatus large amounts of helium are consumed. Various solutions have been attempted to ease the burden of helium shortage including the use of alternate carrier gasses. In our experiments use of an alternate Hydrogen carrier gas was explored as well as use of an innovative He conservation device that limits the flow of helium during sample vaporization in the inlet. The two system configurations were evaluated. The results obtained from the Helium conservation device were compared to results obtained from a system utilizing constant helium flow. Use of hydrogen carrier gas for semi-volatile analysis via 8260 yielded negative long term system effects and unforeseen reactions in the purge and trap apparatus. The helium conservation device produced equivalent results compared to a system utilizing constant helium flow while maintaining original method settings indicating a suitable solution for helium conservation. Comparative volumes of helium consumed during analysis were also evaluated.

### Regulatory implications of advances in bioaccumulation testing and assessment

C. Rauert, Umweltbundesamt / International Chemicals Management; W. Drost, Federal Environment Agency (UBA) / Chemicals; U. Jöhncke, Umweltbundesamt / Chemicals; C. Schlechtriem, Fraunhofer IME / Oekotoxikologie; G. Treu, REACH Chemicals

The bioconcentration factor (BCF) is a well-established metric in bioaccumulation assessment. It reflects the uptake of a chemical in an aquatic organism, commonly fish, from water. In most regulatory systems, a very high BCF is considered an indication of an unacceptable risk. However, in the past years, the assessment of bioaccumulation has experienced some developments that are not yet reflected in the regulatory regimes. For instance, the OECD test guideline for bioaccumulation in fish has been revised in 2012 to incorporate also a second method measuring a biomagnification factor (BMF) following dietary uptake. A definitive criterion has not yet been decided on. BCF and BMF are suitable for moderately and highly hydrophobic compounds, respectively. A suitable screening criterion for hydrophobic compounds is the log  $K_{OW}$ . However, for other substance groups, such as ionising or amphiphilic substances, specific screening criteria are needed. Although it is the most common metric in bioaccumulation assessment, the BCF in fish may not reflect the whole risk. A number of substances have been found that accumulate highly in terrestrial organisms, with only a moderate bioconcentration in fish, e.g. PFOS. A log  $K_{OW}$  between 2 and 5, in combination with a log  $K_{OA} > 6$  has been suggested as screening criteria. Is this a sensible combination of criteria and how should this be reflected in an assessment scheme? Currently, substances with a high potential for accumulation in air-breathing organisms are usually only identified after entering into the environment. Alternative approaches to replace, refine or reduce animal testing in bioaccumulation assessment have been developed. Although it may seem premature to integrate new test methods such as *in vitro* testing into an assessment scheme, this should be considered as early as possible, in parallel to establishing a test guideline, to ensure that the new methods can be used efficiently once methods have matured. This poster aims at showing recent developments in bioaccumulation assessment with regard to their stage of development, regulatory implications and open questions which need to be solved prior to their integration into substance regulations and assessment schemes to improve the quality of bioaccumulation assessment.

## WE212

### Is bioaccumulation in zebrafish embryos purely log-Kow regulated?

D. Kurth, Helmholtz centre for environmental research - UFZ / Department of EffectDirected Analysis; W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect Directed Analysis

With the aim of reducing animal testing, many *in silico* approaches have been developed to model bioaccumulation. To a large extent, those rely on hydrophobicity-based partitioning. However, this purely physico-chemical approach might neglect the active biological contribution to toxicokinetic mechanisms in organisms. In our study, we compare the uptake of organic pollutants from fractionated sediment extract samples into zebrafish embryos, using highly sensitive large volume injection gas chromatography tandem mass spectrometry (LVI-GC-MS/MS). As the sample was separated according to polarity and hydrophobicity, we exposed the organisms to fractions comprising small log  $K_{ow}$ -windows. Hence, we were able to identify compounds with deviating bioavailability to the test organism. Such outliers might show lower bioaccumulation due to biological elimination processes, such as metabolisation or active cellular efflux. Although active efflux reduces the internal concentration of a pollutant at its target site, it does not reduce its internal effect concentrations. In toxicological test systems, external exposure concentrations, responsible the internal effects, increase in the presence of active transport. Consequently, while physico-chemical based equilibrium predictions might be suitable worst-case estimates for chemicals which are actively eliminated by the organism, laboratory-derived external effect concentrations might underestimate toxicity.

## WE213

### A hydrophobicity parameter for surfactants: An estimation of log Kow values for surfactants using RP-HPLC

J. Hammer, University of Utrecht / IRAS; J. Haftka, University of Utrecht / Institute for Risk Assessment Sciences; J.L. Hermens, Utrecht University / Institute for Risk Assessment Sciences; P. de Voogt, University of Amsterdam / IBED

Anionic and nonionic surfactants are large-scale produced chemicals which can be found in many consumer products and consequently also in the environment as organic contaminants. Therefore, it is important to understand the fate and pathways of these compounds. Sorption to soil or bioaccumulation into organisms of these surfactants is mostly driven by the hydrophobicity of the individual compounds. The octanol-water partition coefficient (log  $K_{ow}$ ) is a physicochemical parameter used to describe the hydrophobicity of a substance. However, the conventional methods for determining log  $K_{ow}$  data with the shake-flask or the slow-stirring method (OECD guidelines 107 and 123) are not applicable to surfactants because of their surface-active properties. Instead, OECD guideline 117 allows for the octanol-water partition coefficient to be estimated by using experimentally determined capacity factors for surfactants and reference substances obtained from a reverse phase HPLC method. In this study, log  $K_{ow}$  values for surfactants were estimated by experimentally determining their capacity factors and compare these with capacity factors of reference substances with known log  $K_{ow}$  values. Log  $K_{ow}$  values were estimated for different nonionic and anionic surfactant groups, including alcohol ethoxylates, alkylcarboxylic acids, alkylsulfates, alkylsulfonates, alkylbenzenesulfonates, perfluoroalkylcarboxylic acids, and perfluoroalkylsulfonates. As expected, estimated log  $K_{ow}$  values increased with increasing carbon chain length for substances within each surfactant group. Furthermore, a good correlation was observed between estimated log  $K_{ow}$  values and literature toxicity data such as bioconcentration factors and  $EC_{50}$ . The results show that the current method is a suitable alternative for estimating octanol-water partition coefficients for these compounds. The data will be used in the development of a new hydrophobicity parameter for the prediction of sorption, bioaccumulation, and toxicity of nonionic and anionic surfactants. **Keywords:** Anionic Surfactants; Capacity Factors; Hydrophobicity; HPLC

## WE214

### Protein-water partition coefficients of ionic organic chemicals: Serum albumin and muscle protein as model proteins

L. Oemisch, Analytical Environmental Chemistry; K. Goss, Helmholtz centre for environmental research - UFZ / Department of Analytical Environmental Chemistry; S. Endo, Osaka City University / Urban Research Plaza Graduate School of Engineering

Assessment of the bioaccumulation potential of organic chemicals is required in various regulatory procedures. Currently, the octanol-water partition coefficient is used as screening criteria in most cases. This idea is chiefly based on the assumptions that lipids are the main compartment that accumulates the organic chemicals within the organism, and that solvent octanol serves as a surrogate for lipid phases. These assumptions seem to be acceptable for screening of neutral chemicals. However, for ionic chemicals, neither of the assumptions seem to be valid. An issue is that the protein fraction has been said to have substantial contributions to the accumulation capacity of organisms. Nevertheless, a systematic evaluation has not been conducted for protein-water partition coefficients of diverse organic ions. Moreover, commonly used property estimation tools are basically for neutral compounds and not transferable to ionic species. In this study, we measured protein-water partition coefficients of series of anionic and cationic organic compounds using an equilibrium dialysis method. Bovine serum albumin and chicken muscle protein were used as model proteins. Our first results for selected

chemicals suggest the following trends: Anions show fairly strong binding to serum albumin, whereas cations tend to bind much weaker. Partition coefficients of anions to muscle protein are generally lower than those of serum albumin. In contrast, partitioning of cations to muscle protein appear to be comparable to that of serum albumin. Trends of protein affinity across different ionic chemicals often do not follow the octanol-water partition coefficients of the corresponding neutral species. These initial findings are intriguing and will be followed up in our future work.

##### **Optimizing Immobilized Artificial Membrane Chromatography for Organic Cations**

s.T. droge, Utrecht University / IRAS; S. Mahawat Khan, J.L. Hermens, Utrecht University / Institute for Risk Assessment Sciences

The lipid-water partition coefficient and biotransformation rate constant are for many compounds the main chemical parameters that determine a bioconcentration factor. Immobilized Artificial Membrane (IAM) chromatography columns allow for high-throughput and consistent determination of phospholipid affinities, with medium composition and other system parameters easily controlled. The retention capacity factors ( $k_{IAM}$ ) for most neutral compounds strongly correlate with liposome partition coefficients. However, the ability of the IAM “Drug-Discovery” column to adequately deal with ionized compounds has been questioned. The few available liposome sorption studies on ionizable compounds have shown that the membrane affinity of the ionic species of a base is often less than a factor of 10 lower than the neutral base species, indicating that ionic species should not be neglected in predictions of the bioconcentration potential. A substantial fraction of relevant organic compounds are largely ionogenic in typical environmental conditions as well as physiological conditions, so this strongly hampers the use of IAM as a standard tool to aid environmental risk assessment and pharmaceutical research. The major drawback of IAM is that ionic compounds may undesirably interact with the IAM column material electrostatically due to charged surface moieties that are not related to the phospholipid coating. These moieties comprise weakly acidic free silanol groups and underivatized free propylamine groups. In this study, we explored which medium conditions may be suitable to obtain adequate  $k_{IAM}$  values for 6 fully ionized bases, and why. Our findings show that both salinity and pH of the test medium are key parameters that control the additional Coulombic attraction/repulsion of ions to the IAM column material (IAM.PC.DD2). Using common physiological medium results in an overestimation of membrane affinities of about an order of magnitude for fully charged bases, whereas eluent containing pH7.4 buffers alone (e.g. 10 mM) would result in even higher overestimation. Under optimal conditions, however, IAM-based membrane affinities for fully ionized bases correspond to liposome partitioning data of the ionized species.

#### WE216

##### **Measurements of phospholipid membrane affinity and biotransformation rate constant of ionogenic organic chemicals: Support as refinement for fish bioaccumulation models**

Y. Chen, University of Utrecht / Institute for Risk Assessment Sciences; M.T. Jonker, Utrecht University; J.L. Hermens, Utrecht University / Institute for Risk Assessment Sciences; s.T. droge, Utrecht University / IRAS

Bioaccumulation is one of the key factors in terms of evaluating the fate and risk of chemicals in the environment. Under the chemical legislation REACH, adequate estimates of the bioaccumulation potential of thousands of chemicals, of which 50 % is ionogenic, are required. Only recently, a bioconcentration model specifically for ionogenic organic chemicals (IOCs) in fish has been developed (Armitage et al. 2013) and evaluated against empirical bioconcentration factors (BCFs). While bioaccumulation data on IOCs are scarce, outliers in BCF-IOCs model predictions are related to the uncertainty in and lack of empirical data for phospholipid membrane affinities and biotransformation rate constants. Charged IOCs behave differently than their neutral form and tend to interact with phospholipids through more complex interactions. Additionally, the phospholipid-water partition coefficient is also not sufficient to predict bioaccumulation potential when substantial biotransformation occurs. This study aims to improve the measurement of both parameters for a series of charged organic acids and bases. Solid-supported lipid membranes (TRANSIL) were applied to determine partition coefficients of these selected IOCs at a fixed pH of 7.4. An *in vitro* method using fish liver S9 fraction was used to measure the decrease of the concentration of the parent compound over time. Biotransformation rate constants were then calculated according to the protein concentration and incubation time. The empirical data can be used to improve estimates of the bioaccumulation potential of the tested IOCs and allow for updates of IOC bioaccumulation model parameters.

#### WE217

##### **Expanding the applicability of a mechanistic mass balance model for estimating the bioaccumulation potential of ionizable organic chemicals in fish**

J.M. Armitage, University of Toronto - Scarborough / Department of Physical and Environmental Sciences; T.N. Brown, Dalhousie University / Department of Chemistry; F. Wania, University of Toronto at Scarborough / Department of Physical and Environmental Sciences; D. Mackay, Trent University; J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical Environmental Science

Tools to model the bioaccumulation of neutral organic chemicals (NOCs) in organisms and food webs are well-established in the scientific literature and regulatory practice. More recently, the need to assess the bioaccumulation potential of ionizable organic chemicals (IOCs) has been recognized for ‘B’ categorization, exposure and risk assessment, leading to questions regarding the reliability of available tools for such chemicals. While both regression-based and mechanistic bioaccumulation modeling approaches have been proposed, further development and evaluation are required to build confidence in these tools, particularly for IOCs which are predominantly charged at environmentally-relevant pH (e.g., perfluoroalkylated acids and other anionic surfactants, pharmaceuticals and certain pesticides). The purpose of this study is to present an updated version of a mechanistic mass balance modeling approach for predicting whole body bioconcentration factors (BCF) in fish. The revisions include new treatment of mass transfer at the gill surface and new tools for model parameterization. Results include BCF predictions as a function of external water pH for organic acids and bases, comparisons of modeled and measured chemical uptake rate constants across the gill ( $k_1$ ) and illustrative examples demonstrating the importance of explicitly including biotransformation rate constants ( $k_M$ ) in BCF calculations. The performance of newly developed Quantitative Structure Property Relationships (QSPRs) for estimating the sorption capacity of the organism (e.g. membrane-water partition coefficients and distribution ratios) is also assessed. Key data gaps and research priorities for improving the reliability of this modeling tool are also highlighted.

#### WE218

##### **Predicting biotransformation and bioconcentration of organic chemicals in fish**

J. Stadnicka-Michalak, EPFL - Swiss Federal Institute of Technology; F. Weiss, Eawag - Swiss Federal Institute of Aquatic Science and Technology / Department of Environmental Chemistry; M. Knöbel, Eawag, Swiss Federal Institute of Aquatic Science and Technology / Environmental Toxicology; K. Schirmer, Eawag / Environmental Toxicology

The potential of a chemical to accumulate in organisms is an important criterion in environmental risk assessment. The most commonly applied method to derive bioconcentration factors (BCF) is the Fish Bioconcentration Test, which is technically challenging and resource intensive. Another approach is to predict bioconcentration by means of toxicokinetic models. Here, one-compartment models assume that an organism comprises one tank which contains a well-stirred fluid while multi-compartment models, like the PBTK model, take also tissue distribution of a chemical into account. In their simplest design, both these approaches assume partitioning of chemicals by passive diffusion without taking biotransformation into account. A more realistic way, which includes the *in vitro* biotransformation rate in freshly isolated hepatocytes, has already been introduced. Thus, in our study, we included biotransformation rates in freshly isolated hepatocytes (taken from literature) in both PBTK and one-compartment models to calculate BCFs and compare them to *in vivo* measured BCFs. In addition, as we hypothesized that chemical biotransformation does not take place only in the liver and moreover can be measured also in cultured fish cells, we measured biotransformation rates in three (liver, gill and gut) rainbow trout cell lines. When both (PBTK and one-compartment) modelling approaches accounted for chemical biotransformation in the liver based on biotransformation rates from freshly isolated hepatocytes, the PBTK model outperformed the one-compartment model for predicting BCFs of all chemicals found in the literature. In many cases, these predictions still overestimated measured BCFs, though. For instance for benzo-a-pyrene, including biotransformation in freshly isolated hepatocytes, reduced the BCF from 21000 to 5000 for the one-compartment model and from 9500 to 1700 for the PBTK model, compared to 920 reported for rainbow trout. However, when we applied biotransformation rates from all three cell lines, distinguishing the intestine as important environment-organism barrier, and taking the gill as a representative of other richly perfused tissues in addition to liver and intestine, our PBTK model predicted a BCF of 1060. Thus, our study shows that building a virtual fish from different types of cells may allow to predict internal concentrations even of quickly biotransformed chemicals accurately.

#### WE219

##### **Recent advances in QSAR prediction of fish and human biotransformation half-lives**

E. Papa, Department of Theoretical and Applied Sciences; L. van der Wal, REACH Mastery; J.A. Arnot, ARC Arnot Research & Consulting / Department of Physical Environmental Science; P. Gramatica, University of Insubria / DiSTA

The evaluation of biotransformation processes and rates is an important step in exposure and risk assessment procedures for environmental contaminants. Metabolic biotransformation is a key process, which can lower the Bioconcentration Factor of a chemical in fish below what is expected based on its LogKow alone. Biotransformation in humans and other species is also a key process mitigating bioaccumulation and exposures. Unfortunately, the experimental determination of whole-body *in vivo* metabolic biotransformation rate constants ( $k_M$ ) and half-lives (HL) is expensive and time consuming; therefore, the use of *in silico* techniques, alternative to animal testing, such as Quantitative Structure Activity relationships (QSARs), can be applied to predict missing information of new and existing compounds. In this poster, we present recent

advances in the prediction of biotransformation HL in fish and humans by QSAR models. Two data sets with fish and human biotransformation half-lives for over 1000 organic chemicals were used to build QSARs according to the OECD principles for the validation, for regulatory purpose, of (QSAR) models. Multiple Linear Regression (MLR - Ordinary Least Squares (OLS) method) optimized by Genetic Algorithm Variable Subset Selection procedure, was performed in the software QSARINS using theoretical molecular descriptors calculated from molecular structures as independent variables. External validation was performed by splitting the available experimental data into training and prediction sets and the applicability domain of the models was quantified by the leverage approach. Finally, a combinatorial approach was applied by combining different modelling approaches in order to improve the modelling accuracy and extend the applicability domain of the models. Results from the study show how the recently developed QSARs for biotransformation can be successfully used to fill data gaps, reduce uncertainty in prediction, highlight problematic compounds and focus experimental effort. These models can be successfully applied in Integrated Testing Strategies, as is required in the REACH regulation, at different levels of hazard and risk assessment procedures, and in the refinement of the PBT assessment

T.; D. Nabb, DuPont, Haskell Global Centers; J.W. Nichols, U.S. EPA / ORD NHEERL Mid Continent Ecology Division; C. Schlechtriem, Fraunhofer IME / Oekotoxikologie; H. Segner, University of Bern / Centre for Fish and Wildlife Health; K. Tollefsen, NIVA; L. van der Wal, Organisation for Economic Development and Cooperation (OECD) / Environment Health and Safety Division Environment Directorate; J.A. Weeks, S.C. Johnson & Son, Inc. / Environmental Safety

EU regulations require testing chemicals that have a log Kow > 3 and are produced >100 tons a year for persistence, bioaccumulation and toxicity. Utilizing in vitro biochemical techniques are increasingly demanded to reduce the number of animals used for testing. Chemical biotransformation represents the single largest source of uncertainty in chemical bioaccumulation assessments for fish. In vitro methods employing cryopreserved trout hepatocytes and liver subcellular fractions (S9) can be used to estimate whole-body rates of chemical metabolism. Established in silico models require these rates as inputs to predict chemical bioaccumulation. Predicted levels of accumulation obtained in this manner are generally closer to measured values than predictions obtained assuming no metabolism, suggesting that these methods could provide critical information as part of a tiered approach to bioaccumulation assessment. Regulatory acceptance of these procedures requires, however, that they be evaluated to determine their reproducibility within and among laboratories. Building on previous work, a ring-trial is being led by the ILSI Health and Environmental Sciences Institute (HESI) with the aim to support the development of an OECD test guideline for in vitro fish hepatic metabolism (OECD project 3.13). The approach uses substrate depletion methods to determine the rate at which the in vitro test systems (S9 fractions and cryopreserved hepatocytes) metabolize selected test chemicals. This information can then be extrapolated to the whole liver to provide a direct basis (i.e., ml/h/g liver) for comparison. The ring-trial involves seven laboratories in Europe and North America, and will assess six chemicals in both test systems. The specific aims of this study are to 1) compare performance of the two in vitro assays across participating laboratories; 2) compare S9 method performance to cryopreserved hepatocyte method performance for reproducibility and activity; and 3) provide information required to use the ring trial results for the validation of an OECD test guideline. This poster will provide an overview of the ring-trial study design, timeline, and structure. *The views, conclusions and recommendations expressed in this poster are those of the authors and do not necessarily represent the policies or positions of the European Commission, the OECD, or the United States Environmental Protection Agency*

## WE221

### Comparative assessment of xenobiotic clearance in primary hepatocytes from cold- and warmwater fish species, rainbow trout and common carp

I. Bischof, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; R. Böhm, MVZ Interdisziplinäres Kinderwunschzentrum Düsseldorf GmbH; M. Hüben, H. Jürling, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology; C. Schlechtriem, Fraunhofer IME / Oekotoxikologie; H. Segner, University of Bern / Centre for Fish and Wildlife Health

The standard test for regulatory purposes to determine bioaccumulation of xenobiotics in fish is the OECD TG 305, an in-vivo test which uses a high number of animals (> 100). Recently, *in-vitro* metabolism assays using isolated hepatocytes from fish have been introduced as possible alternative to the *in-vivo*

bioaccumulation test. Currently, work is under way to demonstrate the reproducibility of the method supporting a formal validation. A drawback, however, is that the available *in-vitro* protocols have been developed exclusively for rainbow trout (*Oncorhynchus mykiss*), but not for the other fish species commonly used under TG 305 such as common carp (*Cyprinus carpio*). In order to overcome this limitation and to foster the acceptance of the *in-vitro* method, it must be demonstrated that the protocol is not restricted to one specific fish species. The aim of this study was to evaluate if the existing *in-vitro* methodology for determining xenobiotic clearance in isolated hepatocytes of rainbow trout can be adapted to carp hepatocytes. In a first step, a protocol for isolating carp hepatocytes based on a two-step collagenase-perfusion technique was developed, leading to high cell yield and good cell quality. In a next step, existing protocols for measuring xenobiotic clearance were applied to freshly isolated hepatocytes from trout and carp. As model substances, benzo[a]pyrene (BaP) and methoxychlor (MCX) were used. Incubation temperature for carp hepatocytes was 20°C, while it was 15°C for trout hepatocytes. Irrespective of the higher incubation temperature in the carp assay, xenobiotic clearance rates tended to be lower with carp hepatocytes than with trout hepatocytes. The results from this study demonstrate that the *in-vitro* metabolism assay protocol developed for the cold water species rainbow trout in principal is transferable to other species. What remains to be evaluated is whether the observed differences of the in vitro metabolic rates between carp and trout hepatocytes are able to predict species differences of in vivo xenobiotic metabolism.

## WE222

### In vitro hepatic biotransformation of 14C-decamethylcyclotetrasiloxane (D5) and 14C-decamethyltetrasiloxane (L4) in rainbow trout, carp, catfish, kestrel, quail, rat, mink, and human

D.B. Huggett, Waterborne Environmental, Inc. / Department of Biological Sciences; M. Cantu, D. Hala, University of North Texas / Biology; J. Domoradzki, D. McNett, Dow Corning Corporation

The ability of an organism to biotransform and eliminate chemicals plays an important role in bioconcentration (BCF), bioaccumulation (BAF) and trophic magnification (TMF) assessments. Metabolic potential must be considered when extrapolating from the laboratory to the field, with biotransformation capabilities varying widely across species. Recent efforts have been made in extrapolating *in vitro* fish biotransformation data to a whole body BCF value. By integrating biotransformation estimates into BCF models, a more realistic estimation of BCF can be calculated while providing a cost-effective assay that uses less vertebrate animals. Building on this single species extrapolation concept, biotransformation data from multiple species may be used to construct a biomagnification or trophic magnification model for a given chemical. Using <sup>14</sup>C radiolabelled compounds and high performance liquid radiochromatography, *in vitro* metabolism data utilizing liver microsomes were developed for a cyclic siloxane, D5, and a linear siloxane, L4. Of the species investigated, mink demonstrated the greatest potential to biotransform D5 and L4 siloxanes. <sup>14</sup>C radiochromatograms show the loss of D5 and L4 siloxane, as well as increases in metabolite production over the 60 min incubation period. The percentage loss of D5 was similar with human and rat microsomes and greater than observed with fish. The percentage loss of D5 in birds is low compared to fish and mammals. Similar relationships for loss of parent hold true for L4 (kestrel data not available). These data suggest that D5 and L4 siloxanes are biotransformed by a wide array of species, which can influence "B" assessments. In addition, these data can be used to estimate whole-body rates of metabolism for incorporation into predictive environmental assessment where data gaps exist.

## WE223

### A Critical Review of the Biotransformation of Octamethylcyclotetrasiloxane (D4) and Decamethylcyclotetrasiloxane (D5) in Fish

D.B. Huggett, Waterborne Environmental, Inc. / Department of Biological Sciences Biotransformation is an important physiological process whereby a fish can convert a chemical to a more polar form so that it may be eliminated from the whole body. An understanding of the potential for a chemical to be biotransformed provides important information for a bioaccumulation assessment.

Octamethylcyclotetrasiloxane (D4) and decamethylcyclotetrasiloxane (D5) are widely used in consumer products and industrial applications. These two siloxanes have a high octanol-water partition coefficient (log K<sub>ow</sub> > 6), which is suggestive of a high aqueous bioconcentration factor (BCF). Several studies employing high performance liquid radiochromatography demonstrate that D4 and D5 siloxane are biotransformed into more polar metabolites. A third *in vivo* study employed whole body autoradiography (WBA) and found that a bulk of the <sup>14</sup>C-D4 and D5 radioactivity was associated with the liver, gall bladder and digestive tract during and after exposure. *In vitro* microsomal studies suggest that <sup>14</sup>C-D5 was biotransformed by rainbow trout, while minimal biotransformation was observed with common carp and channel catfish. Using these data-sets, an estimated k<sub>m</sub> for D4 and D5 siloxane is > 0.01 day<sup>-1</sup>. Based on the available data, there is conclusive evidence that D5 siloxane is biotransformed to more polar metabolites in fish. This biotransformation is important and provides rationale for biodilution behavior in food webs (i.e. a TMF < 1).

## WE224

## Metabolism and elimination of 14C-D4 and 14C-D5 in rainbow trout (*Oncorhynchus mykiss*)

J.Y. Domoradzki, R.L. Jezowski, Dow Corning Corporation / Health and Environmental Sciences; D.A. McNett, Health and Environmental Sciences; L. Thackery, J.M. Regan, J. Sushynski, Dow Corning Corporation; J.A. Durham, Dow Corning Corp. / Health and Environmental Sciences; T.A. Springer, T.L. Ross, Wildlife International Ltd; K.B. Woodburn, Dow Corning Corporation / HES; K.P. Plotzke, Dow Corning / Health Environmental Sciences

Whole-body autoradiography (WBA) was conducted in conjunction with dietary bioaccumulation studies with <sup>14</sup>C-D<sub>4</sub> and <sup>14</sup>C-D<sub>5</sub> to assess distribution and metabolism in rainbow trout. For D<sub>4</sub>, fish were fed 15 mg/kg wet wt (ww) during the uptake phase, livers were collected in the depuration phase and analyzed for parent D<sub>4</sub> and total radioactivity. Comparison of radioactivity to D<sub>4</sub> parent concentrations in liver extracts indicated the presence of one or more metabolites. WBA conducted during the depuration phase showed that the highest amounts of radioactivity were present in the digestive tract, liver and adipose tissue, with lesser amounts in other tissues and organs. There was a significant amount of radioactivity in the gall bladder, with moderate amounts in the liver and contents of the digestive tract. Continued presence of parent D<sub>4</sub> in the digestive tract contents at 42 days depuration demonstrates elimination of parent D<sub>4</sub> via enterohepatic circulation. Similarly, a <sup>14</sup>C-D<sub>5</sub> bioaccumulation study analysis of radioactivity concentration and WBA provide evidence that D<sub>5</sub> is metabolized and eliminated via the digestive tract over time. WBA observations during the depuration phase are similar to those found with D<sub>4</sub>. Consistent with metabolism observed in bioaccumulation studies are data from studies where fish were fed radiolabeled D<sub>4</sub> (1-2 mg/kg ww) or D<sub>5</sub> (0.5-1 mg/kg ww) for 4-5 days and whole fish extracts were analyzed for parent and total radioactivity. Percentages of total radioactivity as metabolites were 5% and 31%, for D<sub>4</sub> and D<sub>5</sub>, respectively. Recent *in vivo* 96-h metabolism studies with rainbow trout confirm the WBA findings. Radioactivity detected in the liver for both D<sub>4</sub> and D<sub>5</sub> was due to the presence of metabolites (~40%) as a component of the total radioactivity measured. An important aspect observed in these studies was biliary excretion of metabolites (~95% (D<sub>4</sub>) and 99% (D<sub>5</sub>)) which is indicative of hepatic metabolism. The *k<sub>m</sub>* values for D<sub>4</sub> (0.15 day<sup>-1</sup>) and D<sub>5</sub> (0.17 day<sup>-1</sup>) were determined by modeling blood constituents. Consistent with the *in vivo* findings, is the loss of <sup>14</sup>C-D<sub>5</sub> following incubations with hepatic microsomes from rainbow trout. The work was supported in part by the Global Silicone Industry.

## WE225

### Suitability of terrestrial isopods for bioaccumulation studies

S. Kampe, H. Jüring, Fraunhofer IME Institute for Molecular Biology and Applied Ecology; C. Schlechtriem, Fraunhofer IME / Oekotoxikologie

Physiological differences between aquatic and non-aquatic species (e.g. lung versus gill ventilation) may result in differences in uptake and depuration kinetics of substances between aquatic and terrestrial organisms. Furthermore, fate and behavior of compounds may be completely different in aquatic and terrestrial systems, depending on their physical-chemical properties. The bioconcentration fish test according to OECD test guideline 305 is the standard test design for bioaccumulation assessment (BCF-test). The bioaccumulation potential of substances with very low water solubility can be determined with a dietary bioaccumulation test following the same guideline (BMF-test). The only established test for bioaccumulation assessment on terrestrial animals is conducted with oligochaetes (OECD 317). Test animals are exposed to contaminated soil via multiple uptake routes including porewater, direct dermal contact and ingestion of contaminated sediment particles. Therefore, the test endpoint is defined as a bioaccumulation factor (BAF). A terrestrial test system that enables the estimation of biomagnification factors (BMF) would allow to compare the results with fish BMF data. The terrestrial isopod *Porcellio scaber* is a promising candidate for terrestrial bioaccumulation studies. This species was previously used for toxicity testing, biomonitoring and studies on metal bioaccumulation. A new laboratory test system for bioaccumulation tests with terrestrial isopods was developed. The study design enables the quantification of ingested feed as well as the estimation of growth of the test animals allowing the calculation of kinetic BMFs. A bioaccumulation test with *P. scaber* was carried out with the highly lipophilic (log<sub>K<sub>OW</sub></sub> 5.7) compound hexachlorobenzene (HCB) and the fluorosurfactant perfluorooctanesulfonic acid (PFOS). The animals were fed alder (*Alnus glutinosa*) leaf powder spiked with the test items. Test animals sampled regularly during the uptake (16 d) and depuration phase (16 d) were analysed and the trajectory of tissue concentrations determined. Uptake (*k<sub>1</sub>*) and depuration rates (*k<sub>2</sub>*) were calculated to estimate kinetic BMFs. The bioaccumulation kinetics of both test items in *P. scaber* were compared with uptake and depuration data obtained for rainbow trout (*Oncorhynchus mykiss*) and the earthworm *Eisenia fetida*.

## WE226

### Bioconcentration tests with fish and the freshwater amphipod *Hyaella azteca*. Are the results comparable?

C. Schlechtriem, Fraunhofer IME / Oekotoxikologie; S. Kampe, H. Bruckert, Fraunhofer IME Institute for Molecular Biology and Applied Ecology; C. Schaefer, Fraunhofer-Institut / Ecotoxicology; J. Lharidon, LOREAL / Life Sciences Direction

Bioconcentration factors (BCF) for regulatory purposes are usually determined by fish flow-through tests according to TGD OECD 305. Fish bioaccumulation studies

are time consuming, expensive, and use many laboratory animals. Alternative methods that replace the use of fish for BCF testing would therefore be of value. The aim of this study was to investigate whether the freshwater amphipod *Hyaella azteca* can be used as alternative test organism for bioaccumulation studies, providing the opportunity to explain bioaccumulation from water (bioconcentration). Nine compounds of different lipophilicity (log<sub>K<sub>OW</sub></sub> 3.81-6.92) were tested under flow-through conditions to determine steady-state and kinetic bioconcentration factors (BCF<sub>ss</sub> and BCF<sub>k</sub>). The following substances were tested: hexachlorobenzene, ortho-terphenyl, benzo(a)pyrene, methoxychlor, 1,2,3-Trichlorbenzol, 2,4,5-Trichlorphenol, PCB 153, PCB 77; DB[a,h]anthracene. The results were compared with fish BCF estimates for the same compounds described in the literature. We could show that any of the compounds tested have no potential for bioaccumulation in *H. azteca* while being bioaccumulated in fish, i.e. no "false negative" prediction of bioaccumulation in fish. This means that the *H. azteca* bioaccumulation test could be, which needs to be confirmed by further testing, an appropriate test to predict no significant (BCF < 500) and/or no B-vB classification (BCF < 2000) in the standard fish test. Bioaccumulation studies with *H. azteca* support laboratory animal welfare considerations using a non-vertebrate species, improve efficiency and reduce costs for BCF-testing.

## WE227

### Development and application of sediment bioaccumulation tests for freshwater benthic invertebrates

L.A. Sidney; N. Diepens, Wageningen University / Department of Aquatic Ecology and Water Quality Management; X. Guo, Peking University / College of urban and environmental science; A.A. Koelmans, Wageningen University / Aquatic Ecology and Water Quality Management Group

The variability in bioaccumulation and the relative importance of uptake routes of chemicals across benthic species with different traits is insufficiently understood. We measured and modelled bioaccumulation of PCBs for *Chironomus riparius* (Arthropoda), *Hyaella azteca* (Crustacea), *Lumbriculus variegatus* (Annelida) and *Spharium corneum* (Mollusca). We deployed a novel battery test procedure using multiple enclosures in one aquarium, which maximized equality of exposure for the four species, such that the remaining variability was due mostly to biological traits. The relative importance of uptake from either pore water or sediment ingestion was manipulated by using 28 d spiked standard OECD sediment with low (1%) and medium (5%) OM content and one year spiked (aged) sediment with medium OM content. The ranges in the magnitude of biota sediment accumulation factors (BSAF) were *C. riparius* (3-10) < *S. corneum* (10-17) ≤ *L. variegatus* (7-61) ≤ *H. azteca* (5-114). The high and highly variable BSAF values challenge the presumed value of 1-2 typically employed in ecological risk assessment schemes, and may limit the adequacy of addressing exposure from the pore water only. We argue that enclosure-based battery tests and mechanistic BSAF models improve the quality of the exposure assessment in whole sediment toxicity tests.

## WE228

### A toxicokinetic study of specifically acting and reactive organic chemicals for the prediction of internal effect concentrations in *Scenedesmus vacuolatus*

C. Vogs, Department Bioanalytical Ecotoxicology; A. Kühnert; C. Hug, Helmholtz Centre for Environmental Research / EffectDirected Analysis; E. Kuster, Helmholtz Centre for Environmental Research (UFZ) / Department of Bioanalytical Ecotoxicology; R. Altenburger, UFC Centre for Environmental Research / Department of Bioanalytical Ecotoxicology

Abstract The toxic potency of chemicals is determined well by using the internal effect concentration accounting for differences in toxicokinetic processes and mechanisms of toxic action. This present study examines toxicokinetics of specifically acting and reactive chemicals in the green algae *Scenedesmus vacuolatus* by using an indirect method. Concentration depletion in the exposure medium was measured for chemicals of lower (log *K<sub>ow</sub>* < 3: isoproturon, metazachlor, paraquat) and moderate (log *K<sub>ow</sub>* 4-5: irgarol, triclosan, N-phenyl-2-naphthylamine) hydrophobicity at seven time points over 240 min or 360 min. Uptake and overall elimination rates were estimated by fitting a toxicokinetic model to the observed concentration depletions. The equilibrium of exposure concentrations was reached within minutes to hours or was even not observed within the exposure time. Kinetics of bioconcentration cannot be explained by the chemical's hydrophobicity only, but influencing factors such as ionization of chemicals, an ion-trapping mechanism or the potential susceptibility for biotransformation are discussed. Internal effect concentrations associated to 50% inhibition of *Scenedesmus vacuolatus* reproduction were predicted by linking the bioconcentration kinetics to the effect concentrations which ranged from 0.048 to 7.61 mmol/kg for specifically acting and reactive chemicals. Knowing the time-course of the internal effect concentration may help to understand toxicity processes like delayed toxicity, carry-over toxicity or mixture toxicity in future studies. **Keywords:** Internal dose; Bioconcentration factor; Critical body burden; Toxicokinetic-toxicodynamic modeling

## WE229

### To concentrate or to flux?

N.W. van den Brink, Wageningen University / Dept of Toxicology; M.M. Pereira, CEH; R.F. Shore, Centre for Ecology & Hydrology (NERC)

The quality of our environment can be assessed by various monitoring approaches,

the results of which provide a yardstick against which to quantify change. Results of monitoring activities are generally based on chemical concentrations in environmental compartments and/or selected biological species. However, measurements in different compartments of ecosystems may indicate contradictory trends and it is essential to understand whether concentrations reflect fluxes or environmental load if we are to interpret correctly how environmental inputs and quality are changing. In the presentation we will discuss examples of contrasting trends in concentrations of organohalogen compounds, where declines have been detected in pelagic feeding seabirds but concentrations in benthic and terrestrial organisms have remained stable or even increased. These examples provide evidence that observations on pelagic organisms in marine systems may reflect inputs of contaminants in the system (fluxes), while concentrations in benthic and terrestrial organisms reflect burden or load. Based on this, we propose that consideration should be given to the kinetics of the environmental fate of contaminants when selecting receptors for monitoring. The use of flux-based data may be more appropriate in cases where environmental contaminants may not have reached their final environmental sink and/or when detecting changes in inputs is a primary goal. However, monitoring flux-based concentrations may not predict changes in risk for organisms that are primarily exposed to "load" concentrations. Thus, there may be a need for the development of additional concepts for environmental quality criteria where overall environment is a protection goal.

## WE230

### Exposure characterization of pesticides and primary metabolites in groundwater and human sweat

C. Sweeney, Dalhousie University / Community Health and Epidemiology; J. Kim, Dalhousie University / Community Health Epidemiology; C. Ryan, University of Calgary / Geoscience and BSc Environmental Science Program; J. Guernsey, Dalhousie University / Department of Community Health and Epidemiology  
PEI produces over 30 percent of Canada's total potato production annually. Correspondingly, pesticide use in PEI is substantial, with as many as 20 different pesticides applied to potato crops each season. Several of these pesticides are classified as "probable human carcinogens" by the U.S. Environmental Protection Agency. Pesticides can leach into the highly permeable, fractured sandstone aquifer, contaminating the sole source of drinking water for PEI residents. Although assumed to be minimal, the degree of exposure to pesticides in PEI groundwater is largely unknown. Moreover, the quantitative characterization of pesticide disposition in the body remains unknown. It is hypothesized that considerable amounts of pesticides and their metabolites are excreted in sweat of exposed individuals. The primary objective of this study is to characterize exposure to pesticides and their degradation products/metabolites in groundwater, air, soil and exposed individuals in PEI. To gain greater insight into the exposure characterization of pesticides in the environment and human body, fate and transport of parent compounds and their breakdown products will be examined in PEI environmental samples. The role of eccrine sweat glands in ridding the body of bioaccumulated pesticides will also be investigated through identification and quantitation of pesticides and key metabolites in sweat of exposed individuals; pesticide concentrations in sweat will be compared to those in urine and blood samples of participants. This work will have significant implications for establishing an effective and feasible course of action to reduce or eliminate unacceptable risks associated with environmental pesticide exposure. Future investigations of pesticide bioaccumulation may involve analyses of other biological samples, such as breast milk, hair and nails. Regular sauna therapy could substantially reduce the amount of pesticides that may have bioaccumulated in tissues after years of exposure. Ultimately, pesticide excretion in sweat may be a vital means of eliminating deleterious pesticides that may otherwise accumulate in the body over time and may ultimately lead to the development of cancers.

## WE231

### A comparative study of bioaccumulated pesticide and metal levels in fish from two polluted freshwater dams in South Africa utilised by subsistence, recreational and commercial fishermen.

I. Barnhoorn, Zoology; J.C. Van Dyk, University of Johannesburg; I. Wagenaar, University of Johannesburg / Zoology  
During recent years fish has become an important source of food and especially as a protein source for communities staying in the vicinity of dams with unrestricted access to water. Most of these are subsistence fishermen providing for their families and sometimes they sell fish as a source of income. Between 2005 and 2010 four scientific papers were published on the pesticide and metal concentrations in muscle tissue of the Mozambique Tilapia, *Oreochromis mossambicus*, and sharp-toothed catfish, *Clarias gariepinus*, from the Albasini Dam (AD) and the Rooideplaat Dam (RDPD). Studies regarding organic and inorganic pollutants in fish muscle since then are non-existent or for RDPD limited. During the most recent study at the AD we found that muscle tissue screened positive for a plant growth regulator; DIPN, a N,N-Dimethylalkanamide; Hallcomid M-8-10; 4,4-Bipyridine (Paraquat precursor) and an organochlorine; methoxychlor metabolite. This finding is expected because the AD is situated in an area where agricultural and municipal activities are common in the tributaries feeding the dam. Surprisingly the muscle of fish from the RDPD, situated close to an urban area contained traces of the pesticides lindane, aldrin and dieldrin as reported from a previous study. The results from the current study showed water samples from RDPD had concentrations of

DDT and metabolites, chlorpyrifos, *cis*-chlordane, *trans*-chlordane, dieldrin and aldrin for example. It can therefore be expected that there could be bioaccumulated levels of the same contaminants in fish tissue. Previous human risk analyses (HRA) at both AD and RDPD were a first off and it was recommended that follow-up HRA's be conducted to verify these findings. The results will also allow for the establishment of guidelines for safe fish consumption by humans as well as regulation of harvesting intensity at AD and RDPD.

## WE232

### Magnetic properties of the lichen *Pseudevernia furfuracea* transplanted near a cement plant in NE Italy

D. Kodnik, University of Trieste / Department of Life Sciences; A. Winkler, National Institute of Geophysics and Volcanology; F. Candotto Carniel, University of Innsbruck / Institute of Botany; M. Tretiach, University of Trieste / Department of Life Sciences

The magnetic properties of transplanted samples of the epiphytic lichen *Pseudevernia furfuracea* (L.) Zopf have been analyzed in the framework of a biomonitoring study in NE Italy focused on a cement plant. The lichen transplants were exposed for 2 months in 40 sites distributed all around the cement plant: 37 sites were located at the knots of a 700 m step grid covering agricultural, forest and urban areas and a large industrial zone, and 3 sites were located in nearby urban centers. The samples were analyzed for their elemental content by ICP-MS after a mineralization procedure, and the main magnetic parameters were measured with a AGICO MFK1 susceptibility meter coupled to a CS-3 furnace and a Princeton Micromag Magnetometer in VSM or AGM operating mode. The elemental analysis of the exposed samples revealed a limited impact of the cement plant on the territory, while that of the industrial zone seemed to be generally stronger. The elemental concentration dataset was in substantial agreement with that of the magnetic properties. The cement plant did not have a significant impact on the magnetic properties of the lichens transplanted in the surrounding areas as well. The samples from the industrial area had the highest values of magnetic susceptibility and of saturation/remnant magnetization. The magnetic mineralogy was reasonably uniform throughout the whole set of samples, and was dominated by magnetite in a broad grain-size range. The magnetic mineralogy of the sample nearest to the cement plant was not distinguishable from that of the other lichen samples and did not seem to be clearly linked to the cement therein produced nor to the dusts entrapped by the filter bags of the bag-type dust collector placed inside the chimney above the furnace of the cement plant. The implications of the magnetic characterization of samples on the interpretation of distributional patterns of the air-born particulate matter rich in metals are thoroughly discussed.

## Challenges in Wastewater Treatment and Reuse and the Agricultural Use of Manures and Biosolids (P)

## WE233

### Qualitative and quantitative determination of diclofenac and other pharmaceutical compounds in the WWTPs of Alcantarilla and Mula (Murcia)

C. Fernández-López, UCAM; J. Guillén, J. Padilla, G. Caravaca, UCAM Catholic University of Murcia; A. Lahora, ESAMUR Regional Entity for Sanitation and Wastewater Treatment in Murcia Region; J. Parsons, University of Amsterdam / IBED

The presence of certain pharmaceuticals in grounds and surface waters is a serious environmental problem as these compounds are biologically active and could affect non-targeted and potentially susceptible species. The occurrence of pharmaceuticals in the environment indicates incomplete removal of these drugs from municipal wastewater treatment plants (WWTPs). The first objective of this proposal is to identify and quantify diclofenac and other pharmaceutical compounds in WWTPs of Alcantarilla and Mula to know the influence of these compounds in the aquatic ecosystems. The second objective is to evaluate the relative efficiency of different technologies in eliminating diclofenac and other pharmaceutical compounds and finally to verify if the averaged concentrations of pharmaceuticals in the studied WWTPs could be extrapolated from commercial sales and consumption data. Influent and effluent wastewater in the WWTPs were sampled on one week (5 days consecutive) of February. Pooled samples were collected over a period of 24 hours in automated samplers. Compound concentrations were quantitatively determined with HPLC-DAD. WWTPs of Alcantarilla works with Activated sludge – Double stage, Lamination, Coagulation, Flocculation, Sand filters (SF) and Ultraviolet disinfection (UV) while WWTPs of Mula works with Activated sludge – Extended aeration, Lamination, Coagulation, Flocculation, Disc filters and Ultraviolet disinfection (UV).

## WE234

### Screening treated wastewater for pharmaceutical emerging contaminants under high temperature and saline conditions

D. Nabi, R. Algaoud, D. Tewolde, J. Rodriguez, Masdar Institute / iWater; F. Ahmad, United Arab Emirates (UAE) is one of the world's most highly water stressed countries. Currently, major cities in the UAE depend on energy-intensive desalination technology for water production, which results in a significant

environmental footprint. At present, treated wastewater meets less than 10% of Abu Dhabi city's total water demand indicating a substantial room for improvement with respect to water reuse. We have begun work leading to the sustainable and safe reuse of the treated wastewater in Abu Dhabi, UAE. The recycling of treated wastewater, especially for possible unrestricted end-use, demands a thorough characterization of baseline water quality leading to comprehensive human health and environmental risk assessments for different end-use scenarios. As a first step of this effort, we are screening treated wastewater for emerging contaminants such as pharmaceutical compounds. Initial screening is being conducted using time-weighted passive sampling followed by UPLC-MS/MS and derivatization-GC-MS. In this paper, we report the occurrence of pharmaceutical micropollutants or emerging contaminants in the influent, effluent and sludge samples. We also explore the possible effect of high temperature and salinity conditions in UAE on the occurrence of these chemicals by comparing to reported occurrence in colder regions of the world. **Keywords:** Emerging contaminants, treated wastewater reuse, screening, UPLC-MS/MS

## WE235

### Seasonal changes in the removal efficiencies and concentrations of pharmaceuticals and personal care products (PPCPs) in wastewater and receiving soils (Jerez de la Frontera, SW Spain)

M. Biel, Department of Physical Chemistry; c. corada, University of Cadiz / Physical Chemistry; E. González, University of Cadiz / Department of Physical Chemistry; L. Candela, Polytechnic University of Catalonia; P. Lara, Stony Brook University

Clean water is a key resource for a series of activities, such as agriculture, power generation, and public and industrial supplies. However, wastewater generated by these activities is released into the environment and may represent a potential risk to ecosystems and even human health depending on the presence of certain types and levels of contaminants. This study is focused on pharmaceutically active compounds (PhACs) and personal care products (PCPs), two classes of emerging contaminants (which include commonly used medicinal, cosmetic, and personal hygiene products) that have been widely detected in surface waters over the last years. We have monitored the concentrations of both PhACs and PCPs (both classes also included in the term PPCPs) in influent and effluent wastewater samples from a sewage treatment plant (STP) at Jerez de la Frontera (SW Spain) over a period of 1 year. Overall, simultaneous analysis of 84 pharmaceuticals and 118 PCPs (and some regulated contaminants such as pesticides or polycyclic aromatic hydrocarbons) was performed by means of two methods relying on solid-phase extraction (SPE) - liquid chromatography/mass spectrometry (LC/MS) and stir bar sorptive extraction (SBSE) - gas chromatography/mass spectrometry (GC/MS), respectively. Most target compounds (> 60%) were frequently detected in influent wastewater samples. The highest concentrations were detected in winter and autumn, probably due to lowest biodegradation rates at lowest temperatures. In spite of the Jerez de la Frontera STP showing high removal efficiencies for most chemicals (> 90%), 60 of them were always detected in the final effluent. The highest concentrations here were observed for acetaminophen, caffeine, ibuprofen, galaxolide, OTNE and tonalide, showing average concentrations of 92.9, 75.9, 22.8, 4.0, 2.1, 0.2  $\mu\text{g L}^{-1}$ , respectively. Some target PPCPs such as ketoprofen, diclofenac, nitro musks and galaxolide also showed removal efficiencies that were extremely low (< 10%). Additionally, we carry out several sampling campaigns to collect soils samples from the area, where effluent wastewater from the STP is used for irrigation. Many of the same compounds often detected in effluent samples detected at concentrations between < 1 and 25  $\text{ng g}^{-1}$  in these soils samples.

## WE236

### Metoprolol Metabolites in Microcosm Experiments, Wastewater and Surface Water

A. Sippel, J.E. Yanez Heras, University of Tuebingen / Environmental Analytical Chemistry, Center for Applied Geosciences; C. Zwiener, Environmental Analytical Chemistry, Center for Applied Geoscience, University of Tuebingen / Geosciences Metoprolol is a frequently prescribed drug of the therapeutic class of betablockers used in the treatment of diseases of the cardiovascular system (e.g. hypertension). Its occurrence in wastewater treatment plant effluents and surface waters and its ecotoxicological potential reveals metoprolol as an emerging environmental contaminant. However, the occurrence and fate of metabolites and transformation products of metoprolol in the environment and in water treatment is not well described since mostly analytical methods and pure standards are missing. Therefore new approaches to predict, produce and characterize transformation products and metabolites are highly interesting. In this context electrochemistry (EC) with LC mass spectrometry (LC-MS) has been used for the simulation of enzymatic biotransformation products in living organisms and mainly applied to mimic metabolic pathways in pharmaceutical research. In this work we applied electrochemical flow-through cells (EC) with graphite and diamond electrodes and LC-high resolution mass spectrometry (LC-Q-TOF) to synthesize and characterize metoprolol transformation products (TPs) and to compare the results with those of microcosm experiments and samples from wastewater treatment plants (WTP) and surface water. 25 TPs have been found by electrochemical synthesis and characterized by their mass fragmentation by Q-TOF-MS. Among them are known human metabolites formed by O-demethylation, N-dealkylation, alpha-hydroxylation and oxidation, but also multiply hydroxylated TPs formed by

OH-radical mediated reactions at the diamond electrode. 11 of these TPs have been also found in WTP effluents and in microcosms inoculated with microorganisms from a wastewater impacted river sediment. Only two TPs of a WTP and the microcosms didn't occur in the EC experiments. 5 TPs have been found in surface waters downstream of a WTP. The results reveal degradation pathways which can be easily transferred to other betablockers (e.g. bisoprolol, atenolol) and that EC-LC-MS is a suitable approach to detect new metabolites and transformation products in environmental samples.

## WE237

### Antibiotic residues in the polish coastal zone - conclusions from 5 years study

K. Pazdro; g. siedlewicz, IO PAN / Marine Chemistry and Biochemistry Department; M. Borecka, University of Gdansk / Chemistry Department; A. Bialk-Bielińska, Faculty of Chemistry University of Gdańsk / Department of Environmental Analysis; P. Stepnowski, University of Gdansk / Faculty of Chemistry

In the course of last decade pharmaceuticals have been recognized as relevant environmental contaminants. Special attention should be paid to antibiotic residues. Their continuous input to the environment may strongly affect bacterial populations and induce biological effects in nontarget organisms, potentially disrupting ecosystem processes. Seas can be seen as the final sink of the most persistent antibiotic residues, however the availability of data on antibiotic concentrations in marine environment is still limited. This is particularly true for the Baltic Sea, the sea with large, highly populated catchment area, especially in its southern part. Sediment and water samples were collected during r/v "Oceania" cruises in 2010-2014 period from various locations in the southern Baltic Sea along the polish coast. More than 120 samples were analysed for presence of sulfonamides, trimethoprim, quinolones and tetracyclines. The procedures for the analysis of target compounds applied solid-liquid extraction, SPE disks and tandem SPE technique for isolation, enrichment and clean-up and liquid chromatography coupled with tandem mass spectrometry (LC-MS/MS) with electrospray ionization for final quantitative and qualitative analysis. The validation parameters of the developed procedures showed good precision and accuracy with method limits of quantification ranging from 0.29 to 3.71  $\text{ng g}^{-1}$  d.w. (sediment) and from 0.5 to 10  $\text{ng dm}^{-3}$ . 14 compounds were identified in the samples at concentration levels of a few to tens  $\text{ng g}^{-1}$  d.w. of sediment and of a few to tens  $\text{ng dm}^{-3}$ . The occurrence frequency differed significantly among the compounds. The most frequent compounds were: trimethoprim, sulfamethoxazol, oxytetracycline, enrofloxacin and sulfachloropyridazine. In general, these compounds revealed also the highest concentrations. Occurrence of the identified antibiotics was characterized by high spatial and temporal variability. The results indicate contamination of polish coastal waters and sediments by antibiotic residues. Consequently, the studies should be continued to establish more extensive chemical database on antibiotics and their degradation products in the Baltic Sea area. More detailed ecotoxicological studies should be also developed to assess more accurately ecological risks related to the presence of antibiotics residues in the Baltic ecosystem.

## WE238

### Diazinon and cypermethrin concentrations in wastewater and sludge samples

V. Jones; M. Gardner, Atkins Ltd; B. Ellor, UKWIR

Diazinon and cypermethrin are key components of products used by farmers to control pests on sheep (a process known as 'sheep dipping'). The European Commission Water Framework Directive and Priority Substances Directive set stringent environmental quality standards (EQS) for diazinon and cypermethrin concentrations, due to their high toxicity to aquatic organisms. As part of a wider programme of monitoring (the Chemical Investigations Programme), measurements of cypermethrin and diazinon were taken in water (influent, effluent and throughout the treatment process) and sludge samples from seven wastewater treatment works (WwTWs) across the UK. Despite high removal between influent and final effluent, cypermethrin concentrations in water samples from all works were several orders of magnitude higher than the relevant EQS. This suggests a significant risk of non-compliance with the cypermethrin EQS in receiving waters. Diazinon removal between influent and final effluent was lower than that for cypermethrin, while diazinon concentrations in final effluent samples were above/close to the relevant EQS. Cypermethrin and diazinon concentrations in water samples were significantly higher at one of the sampling sites compared to all other works sampled; this was a site known to receive inputs from the wool textiles industry. Concentrations of cypermethrin and diazinon in sludge were below the limit of detection (0.1  $\mu\text{g/l}$ ) in the vast majority of samples collected in all WwTWs apart from the site affected by wool textile inputs. This comprehensive data set has contributed to our understanding of the presence of sheep dip chemicals in wastewater and sludge.

## WE239

### Untreated sewage as source of NSAIDs in the Río de la Plata river in Buenos Aires, Argentina

M.N. RODRIGUEZ MOREYRA, NATIONAL UNIVERSITY OF LANUS / Department of Productive Development and Technology GAU; G. STERNIK, Sciences Biolab; S.O. Demichelis, Urban Environmental Management / DDPyT The presence of medicines in the environment has become a recent research topic. Non-steroidal anti-inflammatory drugs are weak acids acting by reversible or

irreversible inhibition of one or both isoforms of the cyclooxygenase enzymes, COX-1 and COX-2, involved in the synthesis of different prostaglandins from arachidonic acid. Acetaminophen, aspirin, and ibuprofen are the most commonly used NSAIDs in Argentina (20%, 28%, 50% respectively). Generally, a small portion (1 to 10%) of the ingested are excreted unaltered in urine but some of them could vary from (28 to 60%). In consequence and due to the lack of sewage treatment most of these NSAIDs are expected to be present in the freshwater of the Río de la Plata basin in significant quantities. We evaluated the 3000 surveys that were conducted in streets which included information about 5 age groups evenly distributed ( $X + SD : 20.0 + 1.57$ ) whom were asked about the use of pharmaceuticals in order to relieve general (17.4%), osteo & joints pains (11.2%) or fever (10.3%) in a period of 30 days before the survey (% answered positively); 28.3% of total surveyed respondents said they had used at least one NSAIDs during the period and 4.6% used two different classes and 0.4% used three. An estimation of the annual contribution in Metropolitan Area of Buenos Aires is presented. An extrapolation was performed considering the area served with cloacae sewage, the population size connected to the sewage system, the age pyramid, the average use of each NSAIDs during one month, the diary intake according average weight in each group and duration of treatment, the rate of degradation and the no metabolized excretion rates. Each estimated burden entering annually from cloaca to the river is listed as follows: ibuprofen 1958, aspirin 1388, acetaminophen 656, dipirona 36.0, tramadol 8.28, diclofenac 4.19, ketorolac 0.83, piroxicam 0.62, meloxicam 0.28 and naproxen 0.28 kg/year. The presence of some of these compound were found solved in the water. Many non-target river organisms possess human- and animal-alike metabolic pathways, similar receptors or biomolecules; therefore resulted therefore exposed to these active substances released creating new hazards for the ecosystem equilibrium. Since drinking water is obtained by treatment from water coming from the same river, and tides act as hydraulic cup, it would not be surprising a rise in risks of NSAIDs traces presence in drinking water.

## WE240

### Occurrence of perfluoroalkyl acids in water samples from Vojvodina - the Serbian northern province

B. Skrbic, Faculty of Technology, University of Novi Sad / Faculty of Technology; I. Antic, N. Durisic-Mladenovic, University of Novi Sad Faculty of Technology; K. Kadokami, The University of Kitakyushu

Concerns about the potential environmental and toxicological impact of long-chain perfluoroalkane sulfonic acids (PFSA) and perfluoroalkyl carboxylic acids (PFCAs) have led to the phasing out the production of perfluorooctane sulfonic acid (PFOS) and its precursors. As the result, PFOS and related substances based on PFOS have been listed under Annex B (restriction of production and use) of the Stockholm Convention in 2009. Although the occurrence of perfluoroalkyl acids (PFAAs) in various environmental matrices has been vigorously investigated in the developed countries of the world, to the best of our knowledge there is no study on PFAAs in surface, ground and waste waters of the Vojvodina Province, the Serbian northern part. In order to address this knowledge gap, it has been undertaken a comprehensive survey of 12 PFAAs, which included 9 PFCAs and 3 PFSA in collected samples of waste waters discharged directly to the biggest river flowing through Serbia - the Danube River, surface waters down and up stream of the discharged points along the Danube River and ground waters. The total number of water samples analyzed during this survey was 40. The waters samples were extracted by solid-phase extraction (SPE) with Oasis HLB (225 mg) cartridges and analyzed using ultra-high performance liquid chromatography coupled with tandem mass spectrometry (UHPLC-MS/MS) equipped with a PFC-free Thermo Scientific Accela LC system in order to minimize background contamination of analyzed samples with perfluorinated compounds. The obtained results were used in order: to give an overview on the occurrence of PFAAs in Serbian water samples; to provide a national wide profile of PFAAs level; to find potential sources of PFAAs, to compare the determined levels of PFAAs with the ones found in the other countries and to assess the potential risk of PFAAs on human. Key words: perfluoroalkyl acids, water, occurrence, Serbia Acknowledgment Part of this investigation is realized through EU COST ACTION ES1403-NEREUS and JSPS (Japan Society for the Promotion of Science) Invitation Fellowship Program for Research in Japan, 2014, and supported by Secretariat for Science and Technological Development of the Province of Vojvodina.

## WE241

### Assessment of acute and chronic toxicity in real MWTP effluents treated by different AOPs

S.M. Cuevas, I. Oller, CIEMATPlataforma solar de Almería; M. Llorca, IDAEA, CSIC; C. Sabater, Universidad de Valencia; M. Castillo, Universidad Politécnica de Valencia; S. Rodríguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; A. Agüera, University of Almería / Chemistry and Physics; M. Petrovic, ICRA; P. Fernández-Ibáñez, S. Malato, Plataforma Solar de Almería-CIEMAT Acute and chronic toxicity has been evaluated on samples coming from direct treatment of Municipal Wastewater Treatment Plants (MWTP) effluents (denoted by VCF1) and concentrates obtained by Nanofiltration (NF) membranes of a real MWTP effluent (denoted by VCF4). MWTP effluents were treated by solar photo-Fenton process and ozonation at pilot plant scale under different operating conditions to reach 90% of micro-contaminants elimination: i) Solar photo-Fenton

(0.1 mM Fe(II) and 50 mg/L  $H_2O_2$ ) at pH 3 for VCF1 and VCF4; ii) Solar photo-Fenton at neutral pH with EDDS as complexing agent of iron (Fe(III):EDDS (1:2), 0.1 mM Fe(III), 0.2 mM EDDS for VCF1, 0.2 mM Fe(III), 0.4 mM EDDS for VCF4 and 50 mg/L  $H_2O_2$ ); iii) Ozonation with an inlet ozone concentration of 2.4 gO<sub>3</sub>/h at pH 8. Actual micro-contaminant concentration was monitored by LC/MS/MS (Qtrap 5500). At the end of each tested treatment residual trace of micro-contaminants were observed, mainly 4-AA, 4-FAA, carbamazepine, nicotine and sulfamethoxazole. Acute and chronic toxicity of these samples is compared with toxicity of the parent effluent of the MWTP. *Vibrio fischeri* and cladoceran *Daphnia magna* were selected as test species for analyzing acute toxicity after 30min and 48h of exposure, respectively. *Daphnia magna* was selected as the key bio-test for measuring chronic toxicity after 21 days of exposure. In addition, a photographic study was carried out at the end of chronic analyses where changes in the morphology of *Daphnia magna* due to stress conditions suffered (cicломorphosis) were observed. Solar photo-Fenton process under optimal conditions (pH 3) involved lower toxicity than untreated MWTP effluent, indicating the effectiveness of this tertiary treatment. Toxicity in the sample treated at neutral pH was higher when the EDDS was present at 0.4mM. Higher values of acute and chronic toxicity were measured in samples coming from ozonation. In general, chronic toxicity results showed larger size in exposed females compared to control females and even stimulation commissioning females from untreated samples has been also observed. Finally, decline of mortality in dilute samples (1/2) was high coming to get irrelevant except in the end samples of ozonation.

## WE242

### Ecotoxicological evaluation of treated wastewater and sewage sludge for sustainable use in land management: conclusions from a tiered bioassays-based approach.

E. Richter, ECT Oekotoxikologie GmbH / Aquatic Ecotoxicology Goethe University Frankfurt Main; A. Coors, ECT Oekotoxikologie GmbH Municipal wastewater comprises valuable nutrients but at the same time a mixture of industrial chemicals, biocides, personal care products and pharmaceuticals. As many of these constituents are only partly degraded during wastewater treatment, their more hydrophilic residues remain in the water phase (effluent), whereas their more lipophilic residues sorb to the particulate phase (sewage sludge). Thus, when reusing treated wastewater and sewage sludge in agricultural and landscape management, associated micropollutants may enter and potentially deteriorate the receiving environment. A shortcoming today is that these risks are addressed separately by different legal frameworks, for a limited number of contaminants and isolated for each ecosystem. The present work aimed at assessing the integrated effects of reusing treated wastewater and sewage sludge on land to the environment by applying a tiered experimental approach. Single wastewater-born substances, samples from semi-field experiments and from prolonged field-scale studies were tested for their ecotoxicological effects on representative organisms. As model substances, three azoles and a quaternary ammonium compound were selected, representing different routes of consumption while also differing in behaviour during wastewater treatment. Ecotoxicity was assessed using standard acute and chronic aquatic and terrestrial bioassays. The model substances exhibited high phytotoxicity in water, while their effect concentrations covered a broader and differently ranked range in soil. Effects were not significantly reduced by sludge-amendment to soil. While no risks would be expected from realistic sludge or wastewater application rates, a deterioration of the terrestrial habitat quality cannot be excluded on the long-term. Semi-field experiments on the reuse of treated wastewater supported evidence that soil passage partly improves the habitat quality of wastewater but that this may come at the cost of deteriorating habitat quality of some soils and for some organisms. Thus, it should be carefully decided under which conditions regarding land use and soil properties the benefits from reusing treated wastewater and sewage sludge outweigh the possible deterioration of soil quality. Overall, sewage sludge and treated wastewater constituents may affect both compartments, water and soil, and should therefore be considered in an integrative instead of isolated way.

## WE243

### Efficiently Assessing the Biological Activity of Treated and Untreated Wastewater Using in vitro Cell-Based Assays

A.R. Petosa, McGill University / Chemical Engineering; R. Benoit, Chemical Engineering; M. Marshall, McGill University / Chemical Engineering; L. Taylor, McGill University; V.V. Yargeau, McGill University / Chemical Engineering Municipal sewage treatment plants (STPs) in North America's Great Lakes Basin are point sources for a broad assortment of potential toxins. The inability of STPs to effectively remove anthropogenic materials (e.g., pesticides, pharmaceuticals, personal care product ingredients) may have unforeseen health impacts and harm aquatic organisms and ecosystems. Given the vast array of chemicals present in municipal wastewater, regulating discharges based solely on compound specific chemical analyses may not be sufficient to ensure STP discharge is free of unwanted contaminants. While the removal of specific indicator compounds can be determined with chemical analyses, the use of *in vitro* bioassays enables the toxicity of aquatic matrices containing known and unknown materials to be assessed. Herein, cell-based *in vitro* bioassays were employed to determine whether environmental waters (STP influent, STP effluent, surface water) collected at three STPs in Ontario, Canada's Great Lakes Basin potentially pose health risks. All

samples underwent solid phase extraction and the extracts were then tested with various bioassays including (i) the CellTiter 96® Aqueous One Solution Cell Proliferation Assay (*i.e.*, MTS assay, Promega), (ii) the NRF2 luciferase luminescence assay to monitor cellular antioxidant response, (iii) the ERα CALUX® estrogen receptor assay (Biodetection Systems B.V., Amsterdam), and (iv) the Nuclear Receptors 10-Pathway Reporter Luciferase Kit (Qiagen) to investigate multiple pathway regulation in an MCF7 cell line. Indicator compounds representing a broad range of compound classes commonly encountered in environmental samples were also selected and their presence and removal at the STPs was assessed. Outright cell death was found to be an uncommon occurrence. However, it is evident that exposure to anthropogenic compounds in the extracts impacts the different cell lines, resulting in varying levels of reporter gene expression. Furthermore, chemical analyses demonstrate that the presence of indicator compounds and compound removal efficiencies differ for the three STPs investigated. The findings highlight the importance of employing multiple bioassays to investigate specific and non-specific cytotoxic action, and cell pathway regulation. Overall, combining bioassays with a thorough chemical analysis provides a more complete picture of STP effectiveness in removing emerging contaminants.

## WE244

### Combination of standardized ecotoxicological tests and in situ measurements to characterize the effects of an effluent from a bio-refinery on a freshwater ecosystem.

A. Bado-Nilles, UMRI SEBIO; N. Manier, P. Pandard, INERIS; C. Len, UTC ESCOM; A. Geffard, Université de Reims Champagne Ardenne / Interactions Animal-Environnement (IAE); S. Betoulle, Université de Reims; M. Bonnard, Ecotoxicological Laboratory; J. Porcher, INERIS / UMRI SEBIO

The chemical industry is a very important economic sector in France with used especially oil and their derivatives. Nevertheless, the growing concern of economic world and population contributed to the development of green chemistry notably based on utilization of the biomass. The development of this new type of industry is mediated through the generation of bio-refinery. These bio-refineries are able to transform the agricultural and forest production to bio-energy and bio-product. The present work aims to better understand the ecological and environmental impact of green chemistry on freshwater ecosystem. In this context, some fish and shellfish were caged during 21 days upstream and downstream a bio-refinery of derived glycerin in order to identify potential immunotoxic and genotoxic effects. In the same way, the environmental impact of bio-refinery effluent was characterized in a regulatory context using standardized ecotoxicity tests (e.g mobility of *Daphnia magna*, growth of the unicellular green algae *Pseudokirchneriella subcapitata*, reproduction of *Ceriodaphnia dubia*). The results of this combined approach will be discussed in the poster.

## WE245

### Whole Toxicity Assessment of Industrial and Sewage Effluent in Japan

T. Kusui, Toyama Prefectural University / Faculty of Engineering; Y. Itatsu, Toyama Prefectural University / Faculty of Engineering; J. Jun, Toyama Prefectural University / Faculty of Engineering

To manage the effluent quality, whole effluent toxicity (WET) testing has been introduced in many countries such as USA, Canada, European countries and South Korea. The feasibility of introducing the WET approach into the present regulatory framework in Japan has been under discussion although the draft guidelines for WET testing were released in March, 2013. To grasp the ecotoxic potential of present effluents in Japan, five industrial and four sewage effluents in Toyama Prefecture, Japan were subjected to three freshwater short-term chronic assays. Tests comprised algal inhibition (*Pseudokirchneriella subcapitata*), crustacean reproduction (*Ceriodaphnia dubia*), and fish embryo-larva (*Danio rerio*). Of five industrial effluents, chronic toxic effects on alga, crustacea and fish were observed in four, five and one samples respectively. No-observed-effect concentrations (NOECs) equal to or less than 5% were found in five samples. Heavy metal and basic substances were suspected as the causative factors from initial TIE. The impact of one effluent after discharged into receiving water was assessed by field survey, suggesting the need for improvement of removal efficiency of wastewater treatment plant. As for the municipal effluent, the toxicity on algae was observed in two samples. Residual combined chlorine was suspected as the causative substance. The results of the study show the effectiveness of the whole effluent toxicity approach to compensate the present shortcoming of wastewater regulation in Japan.

## WE246

### Ecotoxicological assessment of wastewater effluents discharges in the Bay of Cádiz. Application of a tertiary treatment: Photobiotreatment

B. Diaz-Garduño, University of Cadiz / Physical Chemical Department; C. Garrido-Perez, CACYTMAR University of Cadiz / Environmental Technologies Department; J. Perales, CACYTMAR University of Cadiz / Department of Environmental Technologies; M. Martin-Diaz, University of Cádiz Center for Marine Science and Technology CACYTMAR / Chemical Physical

Wastewater effluents are widely recognized as a major source of environmental contaminants. Most wastewaters are processed by municipal wastewater treatment plants (WWTPs). Despite the legal requirement for WWTPs, effluents are still considered important sources of pollution for both marine and freshwater

ecosystems. Then sewage effluents are complex mixtures that are known to compromise the health condition of aquatic organisms. Moreover, the environmental repercussions of the discharge of disinfected effluents are still poorly understood. The aim of this study was to determining the environmental risk WWTPs' effluents that are discharged in the Bay of Cadiz (SW, Spain) before and after the application of a detoxification treatment process: photobiotreatment-microalgae culture. Three wastewater treatment plants that discharge to the Bay of Cádiz were selected: La Barrosa (urban wastewater), Puerto Real (urban-hospital wastewater) and El Torno (industrial wastewater). The ecotoxicological assessment of selected effluents was performed applying standardized and recommended short-term toxicity tests using four different organisms and endpoints. Organisms from different trophic levels were chosen as bioindicator species: the bioluminescence response in the bacteria *Vibrio fischeri*, survival in early-stages of the fish *Spaurus aurata*, fertilization and embryo-larval development in the sea-urchin *Paracentrotus lividus* and growth inhibition in the microalgae *Isochrysis galbana*. Results obtained confirmed the suitability of the use of the selected short-term toxicity tests to assess ecotoxicology of selected effluents, being the sea urchin larval development and mortality in fish larvae the most sensitive endpoints. The photobiotreatment significantly reduced effluents ecotoxicity (p<0.05). On the other hand, effluents from the different wastewater treatment plants resulted to increase significantly toxicity (p<0.05) after exposure, since bacteria bioluminescence, survival, growth and reproduction were negatively affected compared with control treatment. Different dilutions of the effluents were analysed in order to propose the incorporation of these short of detoxification treatments to decrease the short-term toxicity that the effluent discharge may cause to the marine aquatic ecosystem of the Bay of Cádiz.

## WE247

### Biomarkers of exposure to whole and elutions of two industrial wastes on *Vicia faba* and *Lactuca sativa*

S. Curieses; W.D. Di Marzio, Universidad Nacional de Lujan-CONICET; J. Alberdi, UNLU; m. saenz, Universidad Nacional de Lujan CONICET

The use of bioassays to evaluate the toxicity of wastes is very important in order to have a more direct and integrated estimate of environmental toxicity. Two industrial wastes, one from foundry sand and the other from cosmetic production were evaluated by means of physico-chemical parameters and exposure biomarkers. Two approaches commonly used in testing of solid wastes may be appropriate for evaluate the ecotoxicological potential of wastes. They are solid phase and water extracts from waste (aqueous elutions). This approach is very important because waster is considered the principal carrier of contamination. The objective of the present study was to compare direct and non-direct approaches using different bioassays and biomarkers in highest plants within a global strategy of ecotoxicological assessment of two industrial wastes. Biomass growth, level of lipid peroxidation, and antioxidative stress enzymes (catalase and peroxidase) were assayed in *Vicia faba* roots for aqueous elutions. Root elongation and seed germination in *Lactuca sativa* assays were performed for solid waste evaluation. A large range of toxicity responses was obtained with the different endpoint analyzed. Whereas root elongation was a sensitive biomarker for both wastes, level lipid peroxidation was not modified regardless of the concentration assayed. The seed germination was inhibited in a dose dependent manner by both wastes. The enzyme activity was inhibited or stimulated according to waste and concentration. The study highlights the importance of to perform a battery of bioassays and biomarkers to assess the ecotoxicity of waste before to final disposal. Comparison of the sensitivity of different endpoint analyzed allows choose the most suitable for regulatory purposes.

## WE248

### Evaluation of hydric resources under influence of a refinery, by ecotoxicological analysis integrated to environmental parameters.

M.M. ROBERTO, UNESP - UNIV ESTADUAL PAULISTA / Department of Biology; M. Hoshina, Unesp - Institute of Biology / Biology; R.V. HARA, C.S. ARAUJO, M.P. SILVA, UNESP - UNIV ESTADUAL PAULISTA / Department of Biology; M.A. Marin-Morales, Unesp - Institute of Biology / Biology; D.D. ANGELIS, UNESP - UNIV ESTADUAL PAULISTA / Department of Biochemistry and Microbiology

The petrochemical industry uses large volumes of water and generates big amounts of effluents. Some industries of this sector have been worrying about the surrounding environment quality, attempting to reduce the impact by treating the wastewater, as well as stimulating the biomonitoring. The largest oil refinery in Brazil is located in Paulínia municipality, São Paulo State, between the Jaguari and Atibaia rivers, which supply the cities of the region. This company gets water from the Jaguari river, treats the wastewater and discharge it in the Atibaia river. The aims of this study were: 1) evaluate the cytotoxicity, genotoxicity and mutagenicity of several water samples collected from these rivers through *Allium cepa* and *Oreochromis niloticus* tests; 2) evaluate those parameters, using the same organisms, on the water samples collected at different stages of wastewater treatment performed by the refinery from 2009 to 2013, and 3) correlate the influence of the physicochemical factors on the endemic biota. The physicochemical analyses were performed and showed that some parameters are in disagreement with current law, affecting the water quality of these rivers. Meteorological data were also registered and showed a correlation with the

recorded cytotoxicity and genotoxicity effects, mainly in the early periods of intense rainfall. The water collected at the refinery collection point and at the upstream of the effluent discharge point have shown worrying toxicity levels, which may be a strong evidence of the influence of other human activities. The meteorological data showed defined hot and rainy seasons (spring and summer) and cooler and drier periods (autumn and winter), which combined to the physicochemical results, were useful to a better comprehension of the biological results. From all the sampled results, a multivariate correlation analysis was performed to determine the main environmental factors that may be directly related to the effects obtained by biological assays. The results of this mathematical method were satisfactory, especially when applied to the data obtained by tests realized with more sensitive organisms, such as fish. From the results of this study we warn that, in spite of the influence of the refinery being small on the biota and the water rivers quality, the monitoring of this area must be constant.

## WE249

### **Cytotoxic, genotoxic and mutagenic effects of humic acids from landfill leachate in plants: an integrative approach using multivariate analysis**

M. Morozesk, UFSCar / Departamento de Ciências Fisiológicas; M. Bonomo, Universidade Federal do Espírito Santo / Departamento de Ciências Biológicas; I.d. Souza, Federal University of Sao Carlos / Department of Physiological Sciences; L. Rocha, I. Duarte, Universidade Federal do Espírito Santo / Departamento de Ciências Biológicas; L.B. Dobbss, University of Vila Velha; E.V. Castro, M.W. Lima, Federal University of Espírito Santo; M.N. Fernandes, Univeridade Federal de Sao Carlos / Ciencias Fisiologicas; S. Matsumoto, Universidade Federal do Espírito Santo

The increasing solid waste production is an important and emergent problem in which landfill disposal represents the most common and appropriate alternative for final disposal. Due to high organic and inorganic pollutant rates present in landfill leachate, proper treatment and disposal methods of this residue becomes extremely important in order to avoid soil and water contamination. Landfill leachate sludge generated after biological treatment is mainly compound by humic substances (HS) that has influence in plant metabolism. Among the HS, humic acids (HA) are commonly study and presents several stimulatory effects in plants due to liberation of bioactive molecules which can access receptors inside or outside the cell. This study aimed to characterize HA extracted from landfill sludge and assess the effects of different exposure doses in plants through chemical and biological analysis, to elucidate the effects of this organic material and minimize potential risks of using sludge in natura. Multivariate statistical methods were applied to datasets using factor analysis (FA) and Spearman's rank correlation coefficient. Landfill HA showed high levels of carbon and nitrogen which may represent an important source of nutrients for plants. The activity of total ATPases and H<sup>+</sup>-ATPases increased in plants treated with higher concentrations of HA tested (2 mM C L<sup>-1</sup>). Additionally, cytogenetic alterations were observed on meristematic and FI cells such as nuclear abnormalities and micronuclei. Multivariate statistical analysis was efficient to integrate data and provide an overview of the physical, chemical and biological results. Thus, despite all nutritional benefits of HA and its activation of plant antioxidant system, the biological effects observed show concern levels of mutagenicity. Due to the residue complexity the use of chemical, genetic and enzymatic analyzes was an important tool for evaluating humic acid application in plants.

## WE250

### **Irrigation with treated wastewater: insights into microbiological implications in soil fertility and in human health**

C. Becerra-Castro, CBQF - UCP / CBQF Centro de Biotecnologia e Química Fina; A. Lopes, Faculdade de Engenharia - Universidade do Porto / LEPABE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia; I. Vaz-Moreira, Escola Superior de Biotecnologia - Universidade Católica Portuguesa / CBQF Centro de Biotecnologia e Química Fina; E.F. Silva, Instituto Politécnico de Viseu / Escola Superior de Tecnologia e Gestão; C.M. Manaia, CBQF Centro de Biotecnologia e Química Fina; O.C. Nunes, Faculdade de Engenharia - Universidade do Porto / LEPABE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia

A review of the current knowledge on soil and wastewater microbiology gives unequivocal indications that the use of treated wastewater for irrigation, in spite of the unquestionable benefits, may have adverse consequences on soil productivity and fertility, and pose serious risks to the environmental and human health. Information currently available shows that physicochemical alterations, such as the increase of organic matter related pools, salinity and soil accumulation of contaminants are frequently observed after irrigation with treated wastewater. The soil microbiota, with a key role on its fertility and productivity, is also known to respond to alterations imposed by wastewater irrigation, presenting an increase of microbial biomass and activity and alterations in community structure. In spite of these observations, the available literature shows that the effects on soil microbiota are neglected when the implications of irrigation with wastewater are discussed.  
**The medium and long term risks for human health posed by wastewater irrigation must also be at the heart of any discussion on wastewater reuse. The evidences reported so far highlight the importance of the accumulation and propagation of biological contaminants in soils due to wastewater irrigation. Indeed, numerous chemical contaminants, such as**

**pharmaceuticals and metals, can threaten the environment and human health. Moreover, the mixture of these contaminants may have unpredictable consequences. Biological contamination by human and animal pathogens, phytopathogens and antibiotic resistant bacteria and their resistance genes must also be taken into account, since once transported by wastewater, they may proliferate and be transmitted over different environmental compartments.**  
**Studies on the effects of wastewater irrigation on soil are challenging, since direct cause-effect relationships can hardly be found. The use of multi-parametric analyses and holistic studies may bring additional and reliable insights into this problem. The maintenance of a rich and diversified autochthonous soil microbiota and the use of treated wastewater with minimal levels of potential soil contaminants are proposed as *sine qua non* conditions to achieve a sustainable wastewater reuse for irrigation.**

**Acknowledgements:** This work was financed by FCT (PEst-OE/EQB/LA0016/2013, PEst-C/EQB/UI0511/2013) and produced under the scope of COST Action ES1403-New and emerging challenges and opportunities in wastewater reuse-NEREU

## WE251

### **Environmental Risk Assessment of Active Pharmaceutical Ingredients in Soils with Emphasis on Wastewater Reuse Practices**

K. Lees, Biogeochemistry Research Group; M. Fitzsimons, Plymouth University; J.R. Snape, AstraZeneca UK Ltd. / AstraZeneca Global Environment; A. Tappin, Plymouth University; S. Comber, Plymouth University / Environmental Science Environmental Risk Assessments (ERAs) of active pharmaceutical ingredients (API) are required as part of a marketing notification in Europe and North America. However, an adverse environmental risk profile is not a barrier to approval or to patient access to medicines. This ERA framework is predominantly focused on assessing the risks that APIs pose to aquatic life. There are currently no requirements for a soil risk assessment to be carried out on APIs which do not strongly sorb to soils, i.e. those APIs with a log K<sub>oc</sub> < 4. However, in emerging markets where sufficient infrastructure and/or waste management is lacking this can lead to the direct discharge of poorly treated or untreated wastewater and/or sludge being applied to agricultural fields. The fate of APIs in wastewater and sludge used on soil has not received much attention and their fate is not well understood in soil. It has been shown in other studies that these chemicals can be present in the soil environment after irrigation with wastewater. The aims of this work are to identify the sources, fate and movement of APIs to soils with particular reference to industrialising countries and produce data to validate existing risk assessment outcomes and to assist in further developing methodologies. Gaps in understanding and exposure pathways of APIs in industrialising countries have been identified as part of a literature review. Key areas addressed as part of this review are (i) lack of knowledge of the amount and types of APIs being consumed, leading to issues modelling concentrations in wastewater; (ii) API removal efficiencies of sewage treatment plants; (iii) movement of APIs to groundwater and other water bodies and (iv) the uptake of APIs by crop plants in these areas due to possible higher concentrations of APIs in wastewater/sludge. Further work as part of this project will include partitioning and degradation studies in soil amended with wastewater and sludge containing priority APIs. The potential outcomes of this research are to provide data for modelling scenarios, to improve ERAs for APIs in soil and to aid understanding of the gaps identified in research.

## WE252

### **UNCSD Rio+20) FOCAL POINT ON INTERNATIONAL WATER COOPERATION**

D.P. Bindra, Civil Aviation / UNCSD Rio Focal Point

The paper aims at contributing to the elaboration of the water-related Sustainable Development Goals and provide concrete guidance on the most pressing Libyan water issues – drinking water, sanitation, waste water treatment, integrated water development & management, international water cooperation, and innovative water technologies needed for manmade river. After giving a background on Agenda 21 adopted at the UN Conference on Environment and Development in Rio de Janeiro, Brazil, in June 1992 the paper focuses on effective ways to make cooperation happen in the water domain. The best approaches to promote effective cooperation at different levels are reflected on how to 'do better' in water cooperation. Based on UNCSD Rio+20 Working Group Discussion Topics numerous Strategic Area in the National Action Plan are identified: 1 Enabling environment, 2 Public-private partnerships, 3. Inter-sector coordination 4. Implementation, 5. Advocacy, 6.Integration, 7. Promotion, 8.Monitoring and evaluation and 9 Research. A case on Environment Aspects of the European Neighborhood Policy (ENP): Water Focus is presented to demonstrate that how New Libya can avail ENPI Funding opportunities for Environment/water related focus.

## WE253

### **Scenarios of bacterial dispersion and climate change in the Marano and Grado Lagoon (Italy)**

I. Scroccaro, ARPA FVG / Osservatorio Alto Adriatico; G. Mattassi, ARPA FVG For a successful aquaculture production diseases coming from virus, bacteria and toxins from harmful algal blooms need to be controlled as much as possible. Further, heavy rainy events due to climate change may affect the environment in farming sites, increasing the risk of spreading of diseases, as well as the

accumulation of pollutants by farmed species. Therefore, mitigation measures and management tools are needed to ensure the development of sustainable aquaculture and to decrease the health-related risks for consumers. In this context modeling may be used as a scientific and technical tool to support the evaluation of water quality and the effectiveness of mitigation measures. In the north-eastern part of Italy, in the Friuli Venezia Giulia Region, the Marano and Grado Lagoon is the most complex transitional ecosystem with the presence of important socio-economic activities in the lagoon, such as traditional fishing and shellfish farming. Numerical simulations of the Marano and Grado lagoon were performed for hydrodynamic circulation, temperature and salinity behavior with the SHYFEM model, a shallow water finite element model developed at ISMAR-CNR in Venice (Ferrarin et al., 2010) and experimental data were used to calibrate the numerical model. The numerical model SHYFEM may be applied also to support the traditional monitoring methods and connect the information concerning the hydrodynamic circulation with the microbiological parameters. In this study scenarios of bacterial dispersion and climate change events in the Marano and Grado Lagoon are investigated with the SHYFEM model. Many simulations have been performed taking into account different input concentration values from the rivers discharging into the lagoon and different survival times for the bacteria. Events of heavy rain are prescribed as boundary conditions and increased water levels are imposed, too. Results are obtained as concentration time series and maps of concentration, in order to investigate the impact of the bacterial load coming from each river. Results show that, due to particular meteo-marine conditions and in case of high input concentration values, some rivers may influence the water quality in the shellfish farming areas. **References** Ferrarin C. et al., 2010. Hydraulic zonation of the lagoons of Marano and Grado, Italy. A modelling approach. *Estuarine, Coastal and Shelf Science*, Vol. 87 (2010), pp. 561-572.

## WE254

### Impact of treated wastewater discharges on the assesment of antibiotic resistance in the environment

C. DAGOT, ENSIL; P. Marie-Cecile, B. Olivier, Université de Limoges / INSERM; C. Magali, Univesité de Limoges; G. Margaux, Université de Limoges / INSERM

The spread of antibiotic-resistant bacteria is a growing problem and a public health issue. Urban Wastewater and Hospital wastewater are considered to be sources for antibiotic resistance dissemination by horizontal gene transfer. Mobile integrons (MI) are genetic elements that acquire, exchange and express antibiotic-resistance genes embedded within gene cassettes (GC). The spread of antibiotic resistance has been monitored on a pilot site in France (<http://www.graie.org/Sipibel/>). It brings together, in one wastewater treatment plant, effluent from the city (Bellecombe, France), and the effluent from a hospital (CHAL, France). Sampling campaigns were conducted on the two types of effluents, upstream and downstream biological treatment facilities, until discharge point in the river (Arve, France). These campaigns measurements were started before the start-up of the hospital activities to have an initial state of the environment. The measured parameters included the classic parameters of pollution, about fifty care activities molecules, assessment of ecotoxic effects and antibiotic resistance. Measuring the amount of integrons directly on the samples and the relative abundance, which is the ratio between the concentration of multiresistance integrons (MRI) and quantification of the gene encoding the 16S rRNA, carries out the evaluation of the global evolution of resistance. The first results showed the presence of antibiotic-resistant bacteria in urban and hospital effluent to similar levels to other treatment plants and hospital effluents also studied. Flows of integrating from urban and hospital effluents are of the same order of magnitude, even if the hospital effluent seems to be more concentrated in antibiotic-resistant bacteria. These concentrations are also followed in the river from the beginning of the sample campaigns showing the evolution of MRI in the environment affected by the water discharge.

## WE255

### Fate of antibiotic resistance genes discharged in wastewater: A Microcosm Study assessing the effect of the autochthonous microbial community and gene host

C. Narciso da Rocha, CBQF - UCP / CBQF; C.M. Manaia, CBQF Centro de Biotecnologia e Química Fina

To assess the risks associated with antibiotic resistance dissemination from a wastewater source, it would be important to improve our knowledge on the fate of genetic determinants and their hosts, and how this fate can be influenced either by the receiving environment or the bacteria or genetic determinants themselves. These were major objectives of this study. Using microcosm assays from hospital effluent, raw wastewater, treated wastewater and sterile ultrapure water, we assessed the fate of the genes *intI1*, *bla*<sub>TEM</sub> and *vanA* harbored by *Acinetobacter johnsonnii* (*intI1*) and *Klebsiella pneumoniae* (*bla*<sub>TEM</sub> and *intI1*), *Escherichia coli* (*bla*<sub>TEM</sub> and *intI1*), *Enterococcus faecalis* (*vanA*) and *Enterococcus faecium* (*vanA*). Microcosms were incubated 15 days at 18 and 30°C, and the fate of these genes was assessed by qPCR. The possible influence of the bacterial gene host and of the autochthonous wastewater bacterial community (DGGE analysis) was assessed. After the incubation period at 18 or 30°C, the number of 16S rRNA and *bla*<sub>TEM</sub> gene copy numbers /ng of DNA in sterile water increased or did not vary depending on the gene hosts used (*K. pneumoniae* or *E. coli*), *intI1* presented a slight increase and *vanA* decreased irrespective of the gene host. In non-inoculated

wastewater microcosm assays, in general, the gene 16S rRNA and *intI1* did not vary, while *bla*<sub>TEM</sub> and *vanA* decreased significantly. In inoculated wastewater microcosms the number of 16S rRNA gene copy number /ng of DNA increased when the *Enterococcus faecalis* and *K. pneumoniae* were inoculated, but not when *Enterococcus faecium* and *E. coli* were used. All the other tested genes harbored by the introduced strains were significantly reduced after 15 days of incubation. No significant variations were observed over the incubation period, neither at 18°C nor at 30°C, for community the richness, diversity and evenness indices. These results suggest that the host of a resistance gene, such as *bla*<sub>TEM</sub>, may influence its fate in the environment. Moreover, it is suggested that genes such as *vanA* and *bla*<sub>TEM</sub> may decay in the environment, either if they are autochthonous in wastewater or inoculated and irrespective of the gene host. However, even below the detection limit, the methods used do not indicate that these genes were eliminated.

## WE256

### Conventional PCR as a low cost method to have an overview of the presence of antibiotic resistance genes in wastewater samples

G. Macedo, CBQF Centro de Biotecnologia e Química Fina; C. Narciso da Rocha, CBQF - UCP / CBQF; C.M. Manaia, CBQF Centro de Biotecnologia e Química Fina

Currently, quantitative real-time PCR (qPCR) is the method of choice to assess the abundance of antibiotic resistance genes (ARG) in environmental samples. Despite the overall reduction of costs, most laboratories handling monitoring analyses may not afford qPCR as routine practice. Therefore, conventional PCR may be considered a good alternative, and the standardization of reliable and easy to perform methods will encourage the routine monitoring of ARG in wastewater samples. Our aim in this work was to ascertain the limit of detection of conventional PCR for some selected indicator genes - class 1 integrase *intI1*, and *bla*<sub>TEM</sub> and *vanA*, in wastewater samples with different characteristics, microbial loads, and total DNA concentrations. As a reference method to assess gene abundance was used qPCR. Samples comprised hospital effluent, and raw and treated wastewater of the municipal wastewater treatment plant receiving the hospital discharge. Total DNA extracts were obtained from 25 and 150 ml of wastewater respectively, filtered through a 0.22 µm-pore polycarbonate membrane, and using the PowerWater DNA Isolation Kit. Conventional PCR assays were performed in DNA extracts in a range of dilutions of 1-100. Using conventional PCR, the limit of detection of the gene *intI1* varied from 1586 to 6 copies/ng DNA (or 5560-203 copies of 16S rRNA gene). For *bla*<sub>TEM</sub> the detection limit varied from 260 to 32 copies/ng DNA (or 12605-5560 copies of 16S rRNA gene). The gene *vanA*, only detectable in municipal wastewater using qPCR, could be detected in hospital effluent DNA extracts with a detection limit of 340 copies/ng DNA (or 5560 copies of 16S rRNA gene). These results suggest that conventional PCR may be a good alternative to qPCR to assess the occurrence of contaminant antibiotic resistance genes in wastewater samples. Critical parameters will be the volume of water to be sampled and the concentration of DNA to test. **Acknowledgements:** This work was performed under the scope of the project 38900 - NEPCAT financed by FEDER funds through ON2 - Programa Operacional Regional do Norte. **Keywords:** real-time PCR; conventional PCR; wastewater reuse; antibiotic resistance.

## WE257

### Quantification of antibiotic resistance genes in wastewater treatment plant and release of resistance genes after the purification process

A. Karkman, Department of Food and Environmental Sciences; T.A. Johnson, Michigan State University / Center for Microbial Ecology Department of Civil and Environmental Engineering; M. Tamminen, University of Helsinki; R.D. Stedtfeld, J.M. Tiedje, Michigan State University / Center for Microbial Ecology Department of Civil and Environmental Engineering; M. Virta,

Antibiotic resistant bacteria have become a serious threat to human health and we might be heading to post-antibiotic era. Major concern is the resistance against last resort antibiotics, such as vancomycin, cephalosporins, carbapenems and quinolones. Wastewater treatment plants are known reservoirs for various antibiotic resistance genes and may serve as hotspots for horizontal gene transfer. The resistance genes from the wastewater treatment plants can eventually end up in the environment either in the effluents or in the sludge. Though antibiotic resistance has been widely studied at wastewater treatment plants, there are few studies characterizing more than few genes or studying the fate of the resistance genes after the purification process. In this study we characterized and quantified genes related to antibiotic resistance and horizontal gene transfer in a large-scale wastewater treatment plant and estimated the release of genes to the environment using a parallel qPCR assay targeting 295 genes. All the results were normalized with 16S rRNA gene copy numbers. Our results show that the distribution of different antibiotic resistance genes changes in the process and that the diversity and abundance of the resistance genes is lower in the effluent and sludge than in the incoming water. Still many resistance genes are released to the environment and could be detected in sediments near the effluent release site. There was also an increase in the relative abundance of some antibiotic resistance and horizontal transfer genes during the purification.

## WE258

### Persistence of resistance genes in sewage canalization networks of a metropolitan area. Relationship between antibiotic selective pressure and

### antibiotic resistance genes

S. Caucci, TU Dresden / Institute of Hydrobiology; A. Karkman, Department of Food and Environmental Sciences; M. Virta; T. Berendonk, Institute für Hydrobiologie

The occurrence of antibiotics in natural and urban environments seems to favor the development and spread of antibiotic resistance. At the same time the key factor for the evolution of new antibiotic resistances is the ability of an organism to adapt quickly to new environmental conditions. One of the environments where the selective pressure of antibiotic pollution could exert an effect on microbial communities is the urban water system. The sewage canalizations and waste water treatment plants in particular are known to carry elevated concentration of pollutants and microorganisms. The co-existence of these two factors could lead to a gradual increase in the prevalence of resistance within the indigenous microbial community. In our study raw waters originated from the sewage pipes of the main neighborhoods of Dresden metropolitan area (Germany) were seasonally collected along the years 2012-13 and screened for the presence and amount of antibiotic resistance genes (ARG). The genes of interest belonged to the chemical classes of  $\beta$ -lactams, quinolones, macrolides, sulphonamides and tetracyclines. Concentrations of antibiotic residues in the raw waters and effluent were measured and the correlation between the amount of prescribed antibiotics antibiotic residues and antibiotic resistance genes revealed via multivariate statistical analysis. Moreover the diversity and species distribution of microbial communities inhabiting sewage waters and effluent will help us to explain the seasonal variation of ARGs content. Overall, despite the sanitation processes the effluent did not show any reduction in ARGs pointing out the need of newer wastewater technologies capable to limit the spread of ARGs in freshwater ecosystems.

### WE259

#### Database mining to evaluate antibiotic resistance hotspot risk in the French sections of the Meuse and Mosel watersheds

M. PONS, LRGP-CNRS-UL / Laboratoire Réactions et Génie des Procédés; C. Merlin, Laboratoire de Chimie Physique et Microbiologie pour l'Environnement Antibiotic resistance is a recent concern in terms of micropollution of aquatic environments and the prevalence data in rivers are still scarce. However the availability of data on the presence of indicator microorganisms such as coliforms, enterococci or *E. coli* is higher. Concentrations of macropollutants such as ammonium which can be linked to untreated or ill-treated municipal sewage, run-off from pastures or leakage from manure treatment facilities are much better documented as well as those of metals (in liquid phase or adsorbed on sediment) and are available in the Rhin-Meuse Agency Information System (<http://rhin-meuse.eaufrance.fr/>). Finally some pharmaceutical residuals are also now monitored. Besides these water quality parameters data on the urban pressure (population distribution in the watershed, consumption of pharmaceuticals, discharges from wastewater treatment plants), industrial activities (steel milling, etc.) as well as on agriculture (distribution of cattle units in the watershed, etc.) can be extracted from different database. Various correlations have been tested between the different data to propose a scheme for assessing the risk for hotspot of antibiotic resistance in the French sections of the Meuse and Mosel watersheds. The results will be discussed with respect to available field data concerning antibiotic resistance.

### WE260

#### Antibiotic resistant bacteria in surface waters downstream of farming and waste water treatment sites

M. Laht, Institute of Technology; K. Telling, University of Tartu / Department of Microbiology; V. Kisand, T. Margus, University of Tartu / Institute of Technology; S. Kõljalg, University of Tartu / Department of Microbiology; P. Kalmus, Estonian University of Life Sciences / Institute of Veterinary Medicine and Animal Sciences; I. Lutsar, University of Tartu / Department of Microbiology; T. Tenson, University of Tartu / Institute of Technology

The antibiotic resistant bacteria have been extensively studied in recent years, and their role as a real threat for human and animal health is recognized. We studied the spread of antibiotic resistant bacteria in surface water bodies down stream of agricultural and municipal waste water treatment sites. The sampling program was focused spatially to small areas in Estonia. The cultivated strains were characterized by whole genome sequencing. Samples were collected during years 2012 – 2014 in total from 16 sampling campaigns covering different seasons. Sampling points were related to 4 farms including samples from animals ( $n=120$ ), slurry ( $n=11$ ) and manure ( $n=10$ ), soil ( $n=18$ ) from fields and surface water from streams and rivers connected to the farms. In addition, the isolates from city (100 000 inhabitants) waste water treatment plant effluent receiving waters were analysed ( $n=3$ ). The analysis was focused on potentially pathogenic bacterial species, such as *Escherichia coli* ( $n=166$ ), *Klebsiella pneumoniae* ( $n=10$ ), *Pseudomonas aeruginosa* ( $n=90$ ) and *Staphylococcus aureus* ( $n=27$ ). All isolates were cultivated on commercially available antibiotic containing selective media that are used in medical and veterinary diagnostics for isolation of the species under study. For determining relations between the isolated strains and for comparison with global databases, MLST analysis was used on seven house keeping gene sequences extracted from the whole genome sequences. The resistance patterns were determined for 10 antibiotics specifically recommended for treatment of the infections caused by studied bacteria, using Epsilon test (E-test). Phenotypic

resistance was compared to the betalactamase genes predicted from the genomic sequences. Our studies show that *Ps. aeruginosa* and *E.coli* strains can spread from agricultural sites and waste water treatment plants to the downstream environments. The high variety of phenotypic resistance in bacteria of the same sequence type suggests rapid horizontal transfer of resistance.

### WE261

#### Beta-lactamases resistance genes and their genomic localization in environmental bacteria

M. Piotrowska, University of Warsaw, Faculty of Biology, Institute of Microbiology / Department of Applied Microbiology; D. Przygodzińska, A. Krawczyk-Balska, M. Popowska, University of Warsaw / Faculty of Biology Biological wastewater treatment plants (WWTP) belong to the specific environments where accumulate a variety of microorganisms and organic biological and chemical pollutants, derived from a variety of sources. Pollutants such as antibiotics and heavy metals cause selective pressure that conditioning maintenance and transfer of antibiotic resistance genes (ARG) in the process of horizontal gene transfer (HGT). The aim of this study was to investigate the presence of  $\beta$ -lactam resistance genes among bacteria isolated from the WWTP and the Vistula river which receives final effluent. To check whether there are differences in the level of bacterial resistance, as well as differences in ARG variety the bacterial strains were isolated from (i) raw sewage, (ii) the bioreactor, (iii) the final effluent and (iv) the river. Among the isolates dominated opportunistic bacteria of the genus *Aeromonas*, characteristic to aquatic environments. As a result have been found confirmed by sequencing genes encoding AmpC, ESBL and MBL  $\beta$ -lactamases. Since most of the identified genes encoding  $\beta$ -lactamases are plasmid-mediated, the structural and functional characterization of the plasmids have been performed.

### WE262

#### Dissemination of antibiotic resistance genes in connection to land application of dairy cattle and swine manure

J. Muurinen, University of Helsinki / Food and Environmental Sciences; M. Ruuskanen, University of Ottawa / Department of Biology; K. Pärnänen, M. Tamminen, C. Lyra, University of Helsinki; M. Virta, The dissemination of antibiotic resistance genes (ARGs) of bacteria to the environment is likely an important factor for the increased prevalence of infections caused by antibiotic resistant bacteria. Farm animal manure is known to contain multiple different resistance genes, as the animals are treated with antibiotics. Agricultural soils and receiving waters are exposed to manure, since it is typically used as a fertilizer by farms. The fertilization with manure most likely increases abundance of ARGs in the environment, but this phenomenon has not been surveyed earlier during normal farming practices. The effects of manure application in the field and runoff waters on two dairy cattle farms and two swine farms were examined in southern Finland. Total DNA was isolated from manure, soil and receiving water samples, collected before and after the storage of manure and fertilization of the soil. The copy numbers of studied ARGs were quantified with qPCR. In most farms the ARGs found in manure had enriched during storage from fall to spring. The relative abundance of antibiotic resistance genes increased clearly from fresh to stored manure. The copy number of detected ARGs was also higher in soil sampled after the fertilization than in soil sampled before. The copy number of ARGs in receiving waters also increased after fertilization. We compared the results against the data of antibiotic usage in farms during the season that the manure was collected for storage. It seems that increased relative abundance of ARGs is not explained by the usage of their "target" antibiotics from past 12 months. Instead the possible co-selection, with example trace amounts of metals, during manure storage might be a considerable factor in the increased relative abundance of ARGs. According to our results, ARGs are disseminated in the environment on Finnish animal farms and it might cause a risk to the animals and workers on the farms, and their immediate surroundings. This dissemination could be perhaps be limited with new manure handling methods, which could reduce enrichment of ARGs in the manure, and subsequently in the environment.

### WE263

#### Comparison of metals and tetracycline as selective agents for development of bacterial community tolerance to tetracycline in agricultural soil

J. Song, P.E. Holm, K.K. Brandt, University of Copenhagen / Department of Plant and Environmental Sciences

Antibiotics have been banned as growth promoters in the EU and the use of antibiotics for animal production is likely to decline in the future due to concerns about environmental selection and spread of antibiotic resistance. By contrast, metals such as copper (Cu) and zinc (Zn) are still widely used as animal growth promoters and may accumulate in agricultural soils receiving animal manures or metal-based pesticides. We hypothesize that Cu and Zn may exert stronger and more persistent selection pressures for development of antibiotic resistance in soil as compared to the antibiotics themselves. We here compare the ability of metals (Cu or Zn) and tetracycline to co-select or select for tetracycline resistance of a bacterial community in an agricultural soil. Model laboratory microcosms were set up by spiking agricultural soil with different levels of Cu, Zn or tetracycline. Pollution-induced community tolerance (PICT) to tetracycline was measured in all microcosms, using the [ $^3$ H]leucine incorporation technique, after 2 months of

community selection. In situ bacterial growth ( $[^3\text{H}]$ leucine incorporation), soil pH ( $\text{pH}_{\text{water}}$ ) and toxicant bioavailability (whole-cell bacterial bioreporters specific for either Cu, Zn or tetracycline) were monitored during the whole community selection phase. Bacterial community tolerance to tetracycline increased significantly in soils spiked with environmentally relevant levels of Cu ( $\geq 333.3$  mg/kg) and Zn ( $\geq 500$  mg/kg), but not in soil spiked with high, unrealistic levels of tetracycline (up to 100 mg/kg). Selection for community-level tetracycline resistance was correlated to the initial toxicant-induced bacterial growth inhibition. We hypothesize that the low selection pressure posed by tetracycline can be explained by low bioavailability of tetracycline in soil (bioreporter measurements pending). In conclusion, our study indicates that toxic metals in soil can exert a stronger selection pressure for resistance development to a specific antibiotic than the antibiotic itself.

## WE264

### Occurrence of antibiotic resistance in marine sediments and fauna along an exposure gradient in Arctic Greenland

M.E. Granberg, Norwegian Polar Institute / Research; I. Dahllof, University of Gothenburg / Department of Biological and Environmental Sciences  
The release of antibiotic/antimicrobial substances into the coastal environment may stimulate antibiotic resistance (AR) in marine bacteria communities. Sewage treatment is generally lacking in Greenland and municipal wastewater is discharged directly into the ocean, likely creating strong gradients of pharmaceuticals from sources into the relatively pristine environment. In accordance with examples from the food industry, we hypothesize that AR bacteria present in the gut of marine organisms may travel from prey to predator along food chains. Greenlandic people traditionally depend heavily on the oceans for food, and our results may thus have implications for the risk of AR exposure to humans. We investigated the correlation between environmental antibiotic exposure and prevalence of AR at three different trophic levels, sediments, blue mussels, fish, along a pollution gradient in Sisimiut, Greenland. During two consecutive summers, sediment, blue mussels (*Mytilus edulis*) and Arctic sculpin (*Myoxocephalus scorpioides*) were collected off the town of Sisimiut, Greenland. Bacteria were cultured from animal gut tissues and sediment samples and tested for resistance towards Penicillin, Ampicillin, Amoxicillin and Ciprofloxacin, ranging from natural to semi-synthetic and synthetic antibiotics. AR bacteria from gut tissues were identified with API tests. There was a strong gradient of AR from point sources to more open waters for all antibiotics, but the magnitudes of resistance and the resistance fingerprints differed among sites. There was also a parallel gradient in the controls with respect to the number of colony forming units, indicating a lower bacterial gut content in fish and mussels closer to sewage outlets. AR bacteria from samples collected closer to the sewage outlet were more often identified as human enterobacteria than AR bacteria obtained further from the source. Results indicate the presence of natural AR in pristine areas and a clear human imprint on bacterial AR in the marine environment around Greenland.

## WE265

### Degradation of cyclophosphamide and ifosfamide by biological treatment and advanced oxidation processes

E. Heath, Jozef Stefan Institute / Env Sciences; M. Česen, JSI; B. Kompare, University of Ljubljana; T. Kosjek, Jozef Stefan Institute / Department of Environmental Sciences  
The trend towards the increasing use of chemotherapy among cancer patients raises questions concerning the presence of cytostatic drug residues in the environment and the impact they have on ecosystems. In the present study, we report on biological treatment using attached-growth biomass on special carriers and various advanced oxidation processes (AOPs) of two cytostatics: cyclophosphamide (CP) and ifosfamide (IF) in aqueous environment. The average removal during biological treatment using attached growth biomass in a flow-through bioreactor with artificial wastewater were 41.2 % and 18.2 % for CP and IF, respectively. In case of biological treatment of hospital wastewater, the removals were slightly higher, 58.9% and 34.9 % for CP and IF, respectively. To achieve higher removal efficiencies, the following advanced oxidation processes were investigated: UV, ozone, UV/ozone, UV/hydrogen peroxide ( $\text{H}_2\text{O}_2$ ), ozone/ $\text{H}_2\text{O}_2$  and UV/ozone/ $\text{H}_2\text{O}_2$ . The optimal conditions for removal were determined regarding the duration of UV and/or ozonation treatment (20 to 120 minutes) and the amount of added  $\text{H}_2\text{O}_2$  (0 – 5000 mg  $\text{L}^{-1}$ ). The highest removal efficiencies, 98.8 % for CP and 94.0 % for IF, were achieved using UV/ $\text{O}_3$ / $\text{H}_2\text{O}_2$  at 5 g  $\text{L}^{-1}$  for 120 minutes. The same treatment was then applied to hospital wastewater, where similar efficiencies were achieved (CP: 98.4 %; IF: 97.9 %). Coupling biological treatment to this AOP (UV/ $\text{O}_3$ / $\text{H}_2\text{O}_2$  at 5 g  $\text{L}^{-1}$ ) for 120 min removed more than 99 % of both compounds. To our knowledge this is the first study to report AOP removal efficiencies of cytostatics from non-treated wastewater. Further work will include ecotoxicity testing of investigated compounds and an assessment of treatment efficiency in terms of toxicity. In addition, occurrence of CP and IF metabolites/transformation products in treated samples will be evaluated.

## WE266

### Reduction of antibiotics & antibiotic resistant Enterococcus in urban wastewater intended for reuse by solar-driven Fenton oxidation

P. Karaolia, Nireas-International Water Research Center, University of Cyprus /

Department of Civil and Environmental Engineering; I. Michael, University of Cyprus / NIREAS International Water Research Center; I. García-Fernández, Plataforma Solar de Almería-CIEMAT; A. Agüera, University of Almería / Chemistry and Physics; S. Malato, P. Fernández-Ibáñez, Plataforma Solar de Almería-CIEMAT; D. Fatta-Kassinos, University of Cyprus / Nireas International Water Research Center

The presence of pathogenic antibiotic-resistant bacteria (ARB) and genes in aquatic environments is an issue of emerging concern, as their incidence has risen due to their continuous exposure to sub-inhibitory concentrations of antibiotics during conventional wastewater (WW) treatment. As urban WW treatment plant effluents are among the main anthropogenic sources of antibiotics into the environment, there is a need of examination of the possible ways of elimination of these mixtures and of ARB in effluents for reuse. In this study, the reduction of a mixture of antibiotics i.e. sulfamethoxazole (SMX) and clarithromycin (CLA) was studied with the use of a HPLC-UV system. In addition, the reduction of *Enterococcus* populations and the removal potential of those resistant to: a) SMX, b) CLA and c) both antibiotics were examined with the use of selective agar media containing the antibiotics, while the toxicity of the treated effluent was examined with the marine bacterium *Vibrio fischeri*. Solar Fenton oxidation using natural irradiation with Fenton reagent doses of 50 mg  $\text{L}^{-1}$  of  $\text{H}_2\text{O}_2$  and 5 mg  $\text{L}^{-1}$  of  $\text{Fe}^{3+}$  at a pilot-scale was used to examine the disinfection and ARB removal in various aqueous matrices. Solar Fenton was more efficient in the removal of enterococci and antibiotics, compared to photolysis. In detail, in all aqueous matrices SMX had higher removal than CLA (95% and 70% removal in real WW, respectively). The disinfection of enterococci in all examined matrices was complete after  $t_{30\text{W},n}=140$  minutes for distilled water and real WW and after  $t_{30\text{W},n}=240$  minutes for simulated WW. The presence of antibiotic-resistant enterococci exhibited a 5-log reduction with solar Fenton in the real WW effluent in the presence of both antibiotics, separately and in a mixture. After treatment, there were 10 times more antibiotic-resistant enterococci in the presence of SMX than in the presence of CLA. Finally, the toxicity of the solar Fenton treated WW to *V. fischeri* remained at low levels throughout the experimental period. Acknowledgements The experimental work was funded by the European Commission under SFERA program (Solar Facilities for the European Research Area, EC Grant agreement no. 228296). Nireas-IWRC (NEA ΥΠΟΔΟΜΗ/ΣΤΡΑΤΗΓΙΚΗ/0308/09) is co-financed by the Republic of Cyprus and the European Regional Development Fund through the Research Promotion Foundation of Cyprus.

## WE267

### Ozonation for the reduction of the microbial load of wastewaters

J.M. Sousa, Faculty of Engineering of University of Porto / Chemical Engineering; M. Pedrosa, Faculty of Engineering of University of Porto; M.F. Pereira, Faculty of Engineering of University of Porto- FEUP / LCM Laboratory of Catalysis and Materials Associate Laboratory LSRE LCM; C.M. Manaia, CBQF Centro de Biotecnologia e Química Fina; A.M. Silva, Faculty of Engineering of University of Porto - FEUP / LCM Laboratory of Catalysis and Materials Associate Laboratory LSRE LCM; O.C. Nunes, Faculdade de Engenharia - Universidade do Porto / LEPABE Laboratório de Engenharia de Processos Ambiente Biotecnologia e Energia

Municipal wastewater treated by conventional methods contains bacterial densities up to  $10^6$  CFU/ 100 ml. To avoid environmental and health risks, the microbial load of treated wastewater should be very low, mainly if its reuse is envisaged. Ozonation is an advanced oxidation processes (AOP) currently used to disinfect water due to its strong biocidal oxidizing properties. This study aimed at assessing the effectiveness of ozonation on the reduction of the microbial load of treated wastewater. A synthetic wastewater containing a mixture of microorganisms (*Escherichia coli*, *Enterococcus faecalis*, *Pseudomonas aeruginosa*, *Acinetobacter johnsonii*, *Rhodotorula rubra* and spores of *Bacillus cereus* and *Aspergillus niger*) was used as a surrogate of secondary treated wastewater. The initial density of each tested bacteria and fungi was of  $10^5$  CFU/ 100 ml and  $10^2$  CFU/ 100 mL, respectively. Ozonation assays were carried out in a lab-scale reactor, with periods of contact of 15, 30 and 60 min. The efficiency of the treatment was assessed based on the enumeration of total heterotrophs (Plate Count Agar) and fungi (Chloramphenicol Agar), faecal coliforms and enterococci (m-Faecal coliforms and m-Enterococcus Agar, respectively) immediately before and after ozonation. Additionally, the ability of cells to recover after ozonation was assessed. Ozonation for 15 min allowed a reduction of the total heterotrophs and fungi of 3 log and 1 log, respectively. Total coliforms and enterococci were more extensively removed, being detected at densities of about 5 CFU/100 mL. However, after 3 days at room temperature, a strong microbial recovery was observed. Total heterotrophs reached  $10^9$  CFU/ 100 mL, while the fungi recovered their initial density ( $10^2$  CFU/ 100 mL). Lower recovery rates were observed for the commensal bacteria (10 CFU/100 mL and 3 CFU/100 mL for total coliforms and enterococci, respectively). After 30 and 60 min of ozonation, the cell counts were below the detection limit (1 CFU/ 100 mL) and cells didn't reactivate after 3 days of incubation, demonstrating the effectiveness of ozonation for wastewater disinfection. Acknowledgments: Financial support for this work was provided by project NORTE-07-0202-FEDER-038900 (NEPCAT), financed by FEDER through ON2 (Programa Operacional do Norte) and QREN. AMTS acknowledges the FCT Investigator 2013 Programme (IF/01501/2013), with financing from the European Social Fund and the Human Potential Operational Programme.

### Photocatalytic decomposition of 5-fluorouracil by treatment with TiO<sub>2</sub> nanoparticles: Kinetics, Transformation Products and routes

A. Koltsakidou, M. Sikiotou, E. Evgenidou, D. Lambropoulou, Aristotle University of Thessaloniki / Chemistry

**Abstract** In the last years, cytostatic drugs' demand in developed countries has grown considerably, due to the high incidence of cancer. Given the concern over the risk posed by the presence of these compounds in water bodies, and hence the possible impacts on public health and aquatic ecosystems a great deal of research is being carried out on technologies for their removal. Among them, photocatalytic treatment process using semiconductors like titanium dioxide (TiO<sub>2</sub>) has emerged as a promising nanotechnology for treating waters contaminated with highly recalcitrant organic contaminants, like cytostatic drugs. In this light, this study explored the application of heterogeneous photocatalysis (TiO<sub>2</sub> in suspension) for the degradation of 5-fluorouracil (one of the most commonly used cytostatic drugs worldwide) in aqueous matrices. For the heterogeneous photocatalysis of 5-fluorouracil, different type of TiO<sub>2</sub> catalysts have been tested and compared with Degussa P-25. Different factors that affect the photocatalytic process were compared: irradiation source, load of catalyst, initial concentration of 5-fluorouracil and pH. Under optimal conditions (100 mg L<sup>-1</sup> TiO<sub>2</sub> at pH 5.8), 10 mg L<sup>-1</sup> 5-fluorouracil can be removed within 45 min ( $k = 0.06 \text{ min}^{-1}$ ) by using Degussa P-25. 5-fluorouracil was found to be decomposed by near-surface <sup>•</sup>OH free radicals produced from valence holes ( $h^+_{vb}$ ). Since little knowledge exists regarding how different types of effluent matrix components affect heterogeneous photocatalytic processes, this paper also investigates in a systematic and quantitative way the effect of suspended particulate matter and selected inorganic and organic matrix constituents on both the adsorption-desorption equilibrium and initial photocatalytic degradation rate of 5-fluorouracil in water. The transformation products generated during the treatment were investigated and characterized by means of liquid chromatography coupled to high resolution mass spectrometry. The main 5-fluorouracil phototransformation pathways were observed to be hydroxylation and fragmentation. Finally, mineralization and ion analysis was performed and a feasible transformation mechanism is proposed.

### Micropollutants removal by algae grown on source separated wastewater

A. Langenhoff, Wageningen University / Environmental Technology; A. Butkovskiy, Wetsus; A. de Wilt, K. Tuantet, Wageningen University; H. Hernandez, Universidad Nacional; T. Fernandes, Netherlands Institute of Ecology (NIOO); G. Zeeman, Wageningen University  
The global increase of population and consequent shortage of natural resources increases the interest in mining of commodities present in waste streams. For example, household wastewater is a potential source of energy, organic matter and nutrients. Source separated collection of toilet wastewater (black water) makes recovery of organic matter and nutrients economically feasible because of their concentration in a relatively small volume. As a result, separated wastewater treatment receives more and more interest. Treatment of black water in a compact anaerobic digester allows conversion of organic matter into biogas. The next step is removal of nitrogen and phosphorous from digested black water or even directly from urine, which can be achieved in a treatment system with algae. The algal biomass becomes enriched with nutrients and can be used as fertilizer. The digested black water will also contain organic pharmaceuticals, as these are insufficiently removed during anaerobic digestion of black water. However, little is known about the removal of pharmaceuticals by algae. Furthermore, the quality of the thus produced algal biomass needs to be studied, as algae can potentially accumulate persistent organic micropollutants within their biomass. This presentation addresses the algal treatment of source separated wastewater and its potential for micropollutants removal. Batch experiments with the microalgae *Chlorella sorokiniana* were performed to assess the removal of six spiked pharmaceuticals (diclofenac, ibuprofen, paracetamol, metoprolol, carbamazepine and trimethoprim) in both digested black water and urine. Additionally, incorporation of these pharmaceuticals and the estrogens estrone, 17 $\beta$ -estradiol and ethinylestradiol into algal biomass was studied. The presence of micropollutants did not inhibit *C. sorokiniana* growth in our experiments. Various removal mechanisms resulted in 60-100% removal of diclofenac and ibuprofen (photolysis), metoprolol (biodegradation) and paracetamol (photolysis and biodegradation) in the treatment system with algae. Transformation of carbamazepine and trimethoprim did not exceed 30% and 60%, respectively. Micropollutants were not incorporated into the algal biomass, as sorption accounted for. This study shows that algal treatment systems have a potential to remove micropollutants from source separated wastewater, and that the produced biomass can be used as a fertilizer.

## WE270

### Greywater as a sustainable water source: an integrated treatment approach coupling photocatalysis and soil columns.

T. Velegraki, Aristotle University; S. Tsoumachidou, Aristotle University of Thessaloniki; E. Diamadopoulos, Technical University of Crete; I. Poullos, Aristotle University of Thessaloniki

Given the worldwide water scarcity and future demands, the debate on the utilization of recycled wastewater as an alternative water source is gaining

increasing attention. One major source of highly reclaimable water, particularly important for water-stressed nations, is the urban wastewater generated from washing activities in a household (laundry, showers, hand basins etc.) which is generally referred to as "greywater" and accounts for up to 75% of domestic wastewater. Bearing in mind that greywater generally has a lower organic load and pathogen content than municipal wastewater which includes additionally the respective streams from toilets and kitchen sinks, it may be considered as an ideal candidate for decentralized treatment and reuse systems. The present study focuses on the application of an integrated system employing titanium dioxide (TiO<sub>2</sub>) photocatalytic treatment technology and soil remediation for the detoxification of simulated greywater. Greywater was synthetically produced in the laboratory, taking into consideration the physical, chemical, and biological characteristics of actual greywater samples taken during an one-month sampling campaign; the sampling campaign was applied at three different sources of greywater i.e. hand basin (COD= 250 $\pm$ 140 mg/L; pH=7 $\pm$ 0.14), shower (COD=347 $\pm$ 274 mg/L; pH=7 $\pm$ 0.17) and washing machine (COD=3343 $\pm$ 1709 mg/L; pH=6.7 $\pm$ 0.98). A simulated effluent was produced composed of various commercial products such as laundry detergent, toothpaste, shampoo and soap. An optimization study was conducted on the photocatalytic degradation of synthetic greywater effluent in order to investigate the influence of various experimental parameters on the degradation kinetics. Results showed that ca. 47% organic content abatement was achieved after 180 min of photocatalytic reaction. The pre-treated effluent was collected and introduced into soil columns so as to assess the efficiency of the land filter method in producing an effluent of high quality for subsequent irrigation purposes. Results showed that the integration of chemical (photocatalysis) pre-treatment followed by a physical/biological (soil columns) polishing step is a highly efficient treatment approach, as it generates an effluent of substantial quality that is safe for subsequent discharge.

## WE271

### Can veterinary antibiotics affect constructed wetlands performance during treatment of livestock wastewater?

C.R. Almeida, CIIMAR University of Porto; A.F. Ferreira, University of Azores / Biology; F. Santos, I. Lourinha, CIIMAR University of Porto; M.C. Basto, CIIMAR and Faculdade de Ciências da Universidade do Porto; A.P. Mucha, CIIMAR University of Porto

Constructed wetlands (CWs) can be used to reduce the various pollutants present in livestock wastewater, such as organic matter, nutrients and metals. Very recently these systems have also been used to remove the so called emergent pollutants. These pollutants can be harmful for both microorganisms and plants, which are key players in CWs removal processes. Therefore, the influence of emergent pollutants, namely antibiotics, on the removal of pollutants from livestock wastewater must be assessed, being this the main objective of the present work. Microcosms (0.4 m x 0.3 m x 0.3 m), simulating CWs, were assembled with *Phragmites australis* to treat livestock wastewater doped or not with 100  $\mu$ g/L of enrofloxacin or of ceftiofur, two antibiotics commonly used in livestock industry. Wastewater was treated during 8 one-week cycle, being afterwards removed and replaced by new wastewater (doped or not). At weeks 1, 2, 4 and 8 treated wastewater was collected and removal rates of nutrients (ammonia and phosphates), metals (Zn, Cu, Fe and Mn), organic matter (chemical oxygen demand (COD) and biological oxygen demand (BOD)), and solids (including total suspended solids (TSS)), as well as, of veterinary antibiotics (enrofloxacin and ceftiofur) were determined. High removal rates (up to 90% depending of the parameter) were observed independently of the presence of the veterinary antibiotics, which were also significantly removed from the wastewater. Generally, measured parameters presented values lower than those expressed in the legislation for wastewater discharge. Present results indicate that, in tested conditions, veterinary drugs presence, namely enrofloxacin and ceftiofur, did not influence significantly the biochemical processes that occur naturally in CWs during treatment of livestock wastewater. Therefore, CWs are a valuable alternative to remove pollutants, including antibiotics, from livestock wastewater, reducing the risk the release of these effluents might pose to the environment. In addition, this technology can be an efficient/economically viable technology to meet the current wastewater reuse challenges. Acknowledgments: To European Regional Development Fund through COMPETE - Operational Competitiveness Program and national funds through FCT, under PEst-C/MAR/LA0015/2013 and ECORISK (NORTE-07-0124-FEDER-000054), co-financed by North Portugal Regional Operational Programme (ON.2 - O Novo Norte), under National Strategic Reference Framework.

## WE272

### Modeling Combined Technological, Environmental and Economic Considerations in Domestic Sludge Reuse via the Analytic Hierarchy Process (AHP)

I. Kalavrouziotis, HELLENIC OPEN UNIVERSITY / SCHOOL OF SCIENCE AND TECHNOLOGY; A. Bick, Bick & Associates; G. Oron, Ben-Gurion University of the Negev / Blaustein Institutes for Desert Research Zuckerberg Water Research Center

An optional method of using recycling and reuse efficiently of sludge is presented. Sludge can be originated from a number of sources, although the one obtained from wastewater is the most common one. It composes around 30% percent of the wastewater treated by activated sludge or other similar methods. It always creates

problems related to the environmental. A multi-objective function is defined. It consists of treating the sludge by four alternatives: (i) disposal of the sludge untreated to the sea; (ii) incineration of sludge for energy generation; (iii) treatment of the sludge via anaerobic digestion, and; (iv) using the treated sludge as a soil amendment, primarily for agriculture. Comparisons of the treatment and disposal method were made. Comparison is based on the Analytic Hierarchy Process (AHP) model. The comparison criteria included similarly also four criteria (more can be used). These criteria included the cleanness of the environment (environmental criteria), the cost of treatment according to the final product, benefit to society in terms of energy generation and benefits to agriculture in terms of food production. There is no doubt that the solutions will be location dependent however, they demonstrate the options in each region. **Key Words:** Sludge; Sludge treatment; Reuse; Recycling; Benefits; Analytical Hierarchical Processes (AHP).

## WE273

### Removal of Carbamazepine by *Phragmites australis* and its endophytic bacteria

A. Sauvetre, Helmholtz Zentrum Muenchen Deutsches Forschungszentrum / Microbe Plant Interactions; P. Schroeder, Helmholtz Zentrum Muenchen / Microbe Plant Interactions

Carbamazepine is an antiepileptic and mood-stabilizing drug used widely in Europe and North America. In the environment, it is found as a persistent and recalcitrant contaminant, being one of the most prominent compounds in the list of hazardous PPCPs found in Waste Water Treatment Plants (WWTPs). *Phragmites australis* is one of the species with a higher detoxification and phytoremediation potential and has been successfully used widely to treat industrial and municipal wastewater. Recently, the identification of endophytic microorganisms from different plant species growing in contaminated sites is providing a list of candidates which could be used as bio-inoculants for bioremediation of difficult compounds. In this study, endophytic bacteria were isolated from *Phragmites* plants originating from a wetland in Eschede, (GE) and exposed afterwards to carbamazepine in perlite under greenhouse conditions. Phylogenetic analysis based on 16S rDNA sequences reveals that the majority of these isolates belong to three groups: Proteobacteria, Actinobacteria and Bacteroidetes. Carbamazepine uptake and plant growth promoting traits were analyzed among the isolates. Regarding their PGP characteristics, the carbamazepine uptake and degradation, and additional characteristics (i.e. denitrification, catalase activity) the best strains were chosen for further inoculation studies Alone or in combination, these isolates could be used as inoculants in constructed wetlands in order to enhance the phytoremediation of carbamazepine in wastewater treatment. **Keywords:** Carbamazepine, Common reed, Endophytic bacteria, Phytoremediation

## WE274

### Uptake of perfluorobutane sulfonate and perfluorooctane sulfonates in rice (*Oryza sativa*)

S. Valsecchi, E. Zenelaj, Water Research Institute - Italian National Research Council IRSA-CNR; M. Mazzoni, Water Research Institute - IRSA-CNR / Water Research Institute; A. Frigerio, Department of Agricultural and Environmental Sciences - University of Milan; S. Polesello, Water Research Institute- CNR / Water Research Institute; M. Rusconi, Water Research Institute - Italian National Research Council / Water Research Institute; S. Gomarasca, Department of Agricultural and Environmental Sciences - University of Milan

The wastewater reuse in agriculture can pose serious environmental and health problems related to the accumulation of the highly soluble emerging pollutants in the irrigated vegetables. Laboratory studies were carried out to assess the uptake mechanisms, translocation and distribution of perfluorooctanesulphonic acid (PFOS) and perfluorobutanesulphonic acid (PFBS), which is a common substitute of PFOS, within rice plant (*Oryza sativa*). Short-term uptake studies (from 4 to 48 h), at high contaminant concentration (1 mg/L) were performed at different pH values (4.5, 5.5 and 6.5), temperature (4° and 20°C) and illumination (darkness and light). In a life-cycle experiment rice plants were grown in hydroponic greenhouse from the seeds to the maturity exposed at 10 µg/L and 100 µg/L of PFBS and PFOS. At maturity the plants were harvested, and roots, stems, leaves, shoot, caryopsis and edible grains were analysed separately. Moreover growth (in term of biomass) and flower fertility (as fraction of fertile flowers) were evaluated. Experiments carried out at different temperature under darkness allowed to assess the transport mechanism of uptake when the transpiration is stopped. Data suggested that the passive diffusion (simple or facilitated) represented 63% and 74 % of the total flow for PFBS e PFOS respectively. Under normal growth conditions, root concentration factor of PFOS (RCF) is 65 L/kg and the uptake constant  $k_u$  is 3.98 L/kg/h which are values very similar to those measured for maize. PFBS uptake is one hundred-fold lower than PFOS one, being RCF 0.69 L/kg and  $K_u$  0.115 L/kg/h. The accumulation in foliage and roots is equivalent for PFBS (the foliage/root concentration factor, FRCF is 0.81), while PFOS preferably accumulates in roots (FRCF = 0.083). Differences in uptake mechanism between PFBS and PFOS have been evidenced also in tests at different pH, from 4.5 to 7: PFBS uptake is independent of the pH value, while uptake of PFOS increases with pH decreasing. Life cycle experiments showed that plants exposed to PFOS and PFBS had a better growth than plants in control experiments and this fact can be explained by considering that perfluorinated sulfonic acids can act as bacteriostatic in the Hoagland solution used as culture medium. Nevertheless even if the biomass growths at 10 and 100 µg/L of

PFOS and PFBS are comparable, at higher concentration of exposition the flower fertility was significantly reduced.

## Developing end-points and effect-based methodologies for characterization of emerging pollutants at relevant exposure concentrations (P)

### WE275

#### Assessment of the Chemical Quality Improvement of Drinking Water Treatment Plants based on Human Health Risk Indexes: The case of Sant Joan Despi Water works by incorporating membrane processes

R. López, CETaqua Water Technology Centre; A. Rubalcaba, Fundació CTM Centre; J. Martín, Agbar; S. Gonzalez; V. Martí, Tecnical University of Catalonia UPC; J.L. Cortina, CETaqua Water Technology Centre

The assessment of the chemical quality improvement of drinking water treatment plants based on health risk indexes has been developed. The methodology used for risk assessment as part of this work considers systemic and carcinogenic effects caused by oral ingestion of water based on the reference data developed by the World Health Organization (WHO) and the Risk Assessment Information System (RAIS) for chemical contaminants. Series of data covering 261 chemical parameters during 5 years (2008-2012) of raw and treated water at the low part of the Llobregat River basin (NE Spain) have been used. After the application of the methodology, resulting global indexes are located below the thresholds except for carcinogenic risk for drinking water, where the risk is slightly above the threshold during 2008 and 2009 before the upgrade of the treatment works with membrane technologies was performed. Annual evolution of indexes shows a decrease on the global risk for all situations: Hq systemic risk based on RAIS descends from 0.64 to 0.42 for surface water and from 0.61 to 0.31 for drinking water; R carcinogenic risk based on RAIS is negligible for surface water and varies from  $4.2 \times 10^{-05}$  to  $7.4 \times 10^{-06}$  for drinking water; W systemic risk based on WHO moves from 0.41 to 0.16 for surface water and from 0.61 to 0.31 for drinking water. A specific analysis for the risk associated to trihalomethanes (THMs) shows the same pattern. Although risk indexes have been calculated in order to help the decision of the stakeholders in charge of water treatment works and administrations dealing with health issues, it is important not to forget that legislation (Directive 98/83/EC) is the main reference when assessing the compliance of water quality to health standards.

### WE276

#### Embryo toxicology and glucocorticogenic activity in JDS3 samples

Y. Shao, Department of Ecosystem Analysis ESA; B. Deutschmann, Institute for Environmental Research RWTH Aachen; J. Kuckelkorn, RWTH Aachen University / Institute for Environmental Research; T. Schulze, W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect Directed Analysis; H. Hollert, RWTH Aachen University / Institute for Environmental Research; T. Seiler, RWTH

One of the key segment that caused the aquatic ecosystem pollution in Danube and many other rivers is organic compounds and their transformation products which may pose a risk to human and environmental health. To evaluate the water quality of Danube river, we present a study in which the embryo toxicology and glucocorticogenic (GR) activity of Danube water organic extracts sampled during the Joint Danube Survey 3 (JDS3) were investigated using the fish embryo test and GR CALUX® assay with zebrafish (*Danio rerio*) and human osteoblastic cells. In this study, all 22 JDS3 samples were collected along the Danube River from downstream, through 10 countries, to the Danube Delta. These water samples were extracted by large-volume solid-phase extraction after removing suspended particulate matter. In order to provide a comprehensive and realistic insight into the bioavailable toxic potential of the surface water, fertilized zebrafish eggs were exposed to these water organic extracts in the range of relative enrichment factor (REF) from 62.5 to 1000(1:2). The result show that embryo toxicity was detectable in all 22 JDS3 samples. 2 samples gave strong toxicity. The LC50 of JDS 32 and JDS 63 was 110.5 and 173.4 respectively. Furthermore, many different malformations and teratogenic effects appeared in this study. The most common cause of lethality due to these samples was coagulation. In a second experiment we tried to detect the glucocorticogenic activity of the samples by means of the CALUX system. The glucocorticogenic activity was detected in 4 out of the 22 sample extracts (JDS 30, JDS 35, JDS 37 and JDS39). The highest activity in JDS 35 and JDS 37 was 0.23 and 0.39 ng Dex-equiv/L respectively. In conclusion, the identity of the compounds responsible for the embryo toxicology is currently unknown. But Glucocorticoids play a pivotal role in the regulation of glucose metabolism and inflammation which may affect biological processes and therefore may cause a threat to aquatic organisms health. Although glucocorticogenic activity was observed only in a few of samples and the concentrations measured were in (low)ng/L range. Chronic exposure should therefore be avoided and the presence of significant levels of glucocorticoids in the environment may be reason for concern. Therefore, more attention should be paid to control the discharge of pollutants in the Danube River.

### WE277

#### Effects of a real-time exposure to an estrogenic effluent on reproduction in the

#### **fathead minnow (*Pimephales promelas*)**

J.E. Cavallin, U.S. EPA; K.M. Jensen, M. Kahl, U.S. EPA / National Health and Environmental Effects Research Laboratory; D.L. Villeneuve, U.S. EPA / Midcontinent Ecology Division; J.M. Mayasich, WLSSD; K.E. Lee, U.S. Geological Survey; A. Schroeder, US EPA / Water Resources Center; E. Eid, U.S. EPA, Mid-Continent Ecology Division; K. Nelson, United States Environmental Protection Agency / Toxic Effects Branch; R.Y. Milsk; B.R. Blackwell, US Environmental Protection Agency; M. Lee, US EPA; J.P. Berninger, USGS - CERC / BiochemistryPhysiology; C.A. LaLone, C. Blanksma, U.S. EPA; R.D. Johnson, U.S. EPA / ORD/NHEERL/MED; G.T. Ankley, U.S. EPA / National Health and Environmental Effects Research Laboratory

Wastewater treatment plant (WWTP) effluents are a well-established point of convergence through which anthropogenic chemicals enter surface waters. Whole effluent testing guidelines were developed to screen these complex mixtures for acute toxicity. However, effects-based approaches for evaluating effluents or surface waters for more subtle, sublethal effects of contaminants are lacking. Of specific concern are contaminants such as pharmaceuticals and pesticides that could affect endocrine function through action on the estrogen or androgen receptors or inhibition of sex steroid synthesis. The present study employed an effects-based approach using a historically estrogenic WWTP effluent to assess potential chronic effects of contaminants on different biological pathways. Specifically, a 21 d reproduction study using fathead minnows was conducted on-site at a WWTP using a continuous flow-through testing system that delivered final treated effluent in real-time. Breeding pairs of male and female fathead minnows were exposed to control water and three effluent dilutions (5%, 20%, and 100%). Molecular and biochemical endpoints representing key events along established adverse outcome pathways linking estrogen receptor (ER) activation, and other relevant endocrine molecular initiating events, to reproductive impairment in fish were examined. In order to compare biological effects with chemical composition and in vitro estrogenic activity of the effluent, 7 d composite effluent samples were collected for chemistry and in vitro bioassays. Chemistry results were used to construct a chemical-gene interaction network to aid in targeted gene expression analyses. Cumulative fecundity was significantly reduced in fish exposed to 100% effluent and increased in those exposed to 20% effluent (the approximate dilution factor in receiving waters). The most potent estrogen detected in the effluent was estrone, and estrone concentration trends aligned with in vitro ER activation. Male vitellogenin mRNA transcript abundance and plasma protein concentrations increased in a dose-dependent manner with effluent concentration. Although predictable biological responses to ER agonism were observed, given the nature of chemical mixtures, additional pathways were evaluated. Results of the study provide insights into the significance of pathway-based effects with regard to predicting adverse reproductive outcomes. *The contents of this presentation do not constitute official EPA policy.*

#### **WE278**

##### **Exposure of zebrafish (*Danio rerio*) to bisphenol AF impairs reproduction and performance of offspring generation**

B. Kwon, Dept. Occupational and Environmental Health / Department of Environmental Health; S. Jang, Dept Occupational and Environmental Health; B. Kim, Department of Environmental Health; K. Ji, Yonjin University

While bisphenol AF (4,4'-hexafluoroisopropylidene-2-diphenol, BPAF), a fluorinated derivatives of bisphenol A (BPA), has been detected both in the environment and biota, limited information is available on the effects of endocrine system in fish. Potential effects from parental transfer to BPAF in fish are of concern but such information is not yet available. In the present study, endocrine disrupting effects of BPAF on reproduction in adult zebrafish (*Danio rerio*) and its effects on their offspring generation following parental exposure to BPAF were investigated. Adult zebrafish pairs (*D. rerio*) were exposed to environmentally relevant concentrations (0, 0.5, 5, 50 µg BPAF/L) for 21 d, and the effects on reproduction, somatic index, sex steroid hormones, and transcription of the genes belonging to the hypothalamic-pituitary-gonad (HPG) axis were investigated. The adverse effects on performances of F1 generation were further examined with or without subsequent exposure to BPAF. The average number of eggs spawned was significantly less upon the exposure to ≥0.5 µg BPAF/L. The effective concentrations for reproduction of BPAF were similar to those of bisphenol S (BPS), suggesting the endocrine disruption potential of BPAF is no less than that of BPS. Gonadosomatic index (GSI) in male and female fish reduced significantly at ≥5 and 50 µg BPAF/L, respectively. The results of hormone and gene expression assay showed that BPAF could alter steroidogenic pathway. Parental exposure to BPAF resulted in delayed hatching when continuing exposure to 50 µg BPAF/L, same concentration as their parents. Continuous BPAF exposure in the F1 embryos resulted in reduced survival and increased malformation rate. The results of our study showed that the exposure to BPAF could affect reproduction function of zebrafish and development of its offspring generation. Given the extensive use of BPAF and their loadings to the environment, further investigations on potential consequences in mixture situation are recommended. *Acknowledgement* – This study was supported by National Research Foundation of Korea (NRF; Project no. 2013R1A1A1061684).\n

#### **WE279**

##### **ENVIRONMENTALLY RELEVANT CONCENTRATIONS OF**

##### **GALAXOLIDE (HHCB) AND TONALIDE (AHTN) CAUSED OXIDATIVE AND GENETIC DAMAGE IN *Dreissena polymorpha***

M. Parolini, University of Milan / Biology; S. Magni, University of Milan; C. Della Torre, University of Siena / Department of Physical Earth and Environmental Sciences; S. Villa, University of Milano-Bicocca; A. Finizio, University Milano - Bicocca; A. Binelli, University of Milan / Department of Biosciences  
Synthetic musk compounds (SMCs) are extensively used as fragrances in several personal care products and have been recognized as emerging aquatic pollutants. Among SMCs, galaxolide (HHCB) and tonalide (AHTN) are extensively used in several products of daily use and have been measured in aquatic ecosystems worldwide in the ng/L-µg/L range. Despite of the increasing awareness regarding their environmental occurrence, their potential risk to aquatic non-target organisms remains largely unknown. The aim of this study was to investigate the bioaccumulation of HHCB and AHTN after 21-day exposure to two environmental concentrations and to assess whether they can induce oxidative and genetic damage in the freshwater bivalve *Dreissena polymorpha*. The lipid peroxidation (LPO) and protein carbonyl content (PCC) were measured as oxidative stress indexes, while the DNA precipitation assay and the micronucleus test (MN test) were applied to investigate the onset of genetic injuries. Both musks were accumulated in zebra mussel soft tissues according to concentration-dependent relationships. HHCB induced significant increases in LPO and PCC levels, while AHTN enhanced only protein carbonylation. Moreover, significant increases in DNA strand breaks occurred upon exposure to the highest tested concentrations of both HHCB and AHTN, but no fixed genetic damage was observed, as pointed out by the lack of significant increase of micronucleated cell frequency. Comparing the results obtained at a similar tested concentration, AHTN caused higher oxidative and genetic damage to the zebra mussel than HHCB, highlighting its higher toxicity compared to HHCB towards our biological model. In conclusion, our data showed that the exposure to realistic concentrations of HHCB and AHTN can affect the health status of the zebra mussel, suggesting the necessity of further in depth investigation to confirm their hazard to aquatic ecosystems.

#### **WE280**

##### **COMPARISON OF TOXICITY INDUCED BY SOME ILLICIT DRUGS TO THE ZEBRA MUSSEL**

S. Magni, University of Milan; C. Della Torre, University of Siena / Department of Physical Earth and Environmental Sciences; M. Parolini, University of Milan / Biology; A. Binelli, University of Milan / Department of Biosciences  
Illicit drugs are considered emerging aquatic contaminants because of their high use worldwide and the inability of traditional wastewater treatment plants (WWTPs) to efficiently remove them from sewage. Although their occurrence in the aquatic ecosystems is well-known, the investigation regarding their potential toxicity on aquatic communities is in its infancy. Therefore, the aim of this study was to evaluate the sublethal effects caused by some common illicit drug residues found in the aquatic ecosystems, namely Δ-9-tetrahydrocannabinol (Δ-9-THC), morphine, 3,4-methylenedioxymethamphetamine (MDMA), amphetamine, benzoylecgonine and ecgonine methyl ester, on the freshwater bivalve *Dreissena polymorpha* through a biomarker battery. For each tested compound, we exposed the bivalves at the same concentration (0.5 µg/L) for 14 days. Cytotoxicity was analyzed by the Neutral Red Retention Assay while, to assess the onset of oxidative stress, we monitored the activity of antioxidant enzymes, namely catalase, superoxide dismutase and glutathione peroxidase, the phase II detoxifying enzyme glutathione-S-transferase, as well as the levels of lipid peroxidation and protein carbonylation. Lastly, genotoxicity was evaluated on bivalve haemocytes by Comet test, Micronucleus Test and DNA Diffusion Assay. The obtained results were then incorporated into a sintetic index, called biomarker response index (BRI), to draw a toxicity scale on the basis of the effects observed with each individual biomarker. The obtained results showed that the Δ-9-THC is the most toxic drug to the zebra mussel, since it induced oxidative stress and the consequent oxidative and genetic damage. The two cocaine metabolites (benzoylecgonine and ecgonine methyl ester) appeared to have a lower environmental toxicity compared to Δ-9-THC, while morphine, MDMA and, above all, amphetamine exhibited the lowest toxicity, at least for the considered end-points. This study represents the first screening performed for the evaluation of the sublethal effects of different illicit drugs and encourages future research about the chronic toxicity evaluation.

#### **WE281**

##### **UPTAKE AND DISTRIBUTION OF CARBAMAZEPINE AND METABOLITES IN DIVERSE ORGANS OF *Jenynsia multidentata*, CHANGES IN THE ACTIVITY OF ACETYLCHOLINESTERASE.**

M.E. Valdés, School of Chemical Sciences. National University of Córdoba.; L. Bertrand; M.D. Bistoni, Universidad Nacional de Córdoba / FACULTAD DE CIENCIAS EXACTAS FÍSICAS Y NATURALES IDEA; B. Huerta Buitrago, Catalan Institute for Water Research (ICRA) / Department of Water Quality; S. Rodriguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; D. Barcelo, IQAB-CSIC / Institute for Environmental Assessment and Water Research; D.A. Wunderlin, Universidad Nacional de Córdoba / ICYTAC DPTO QUÍMICA ORGÁNICA FACULTAD DE CIENCIAS QUÍMICAS  
Pharmaceuticals are emerging contaminants ubiquitously found in watercourses, whose ecotoxicological and human risk is still under research. In the Suquia River basin (Córdoba, Argentina), atenolol, carbamazepine and diclofenac were the

pharmaceuticals most frequently detected downstream the WWTP of Córdoba city. *Jenynsia multidentata* is a widespread native fish proposed as bioindicator in the basin. The goals of this work were: 1) to optimize a methodology for the analysis of pharmaceuticals in small organs of fish, 2) to analyze the bioconcentration and distribution of carbamazepine (CBZ) in organs of *Jenynsia multidentata* and 3) to measure changes in acetylcholinesterase (ACh) activity after exposure to CBZ, as a biomarker of neurotoxic early effects. An extraction methodology was optimized for the analysis of 20 pharmaceuticals in freeze-dried small amounts of fish organs (25 mg dry weight of liver, intestine, muscle, gills and 10 mg dw of brain), by ultrasonication with methanol and solid phase extraction as clean-up<sup>1</sup>. Separation and detection were accomplished by UHPLC-MS/MS following an already validated method. This method was applied to quantify CBZ and 2 metabolites (10,11-epoxyCBZ and 2-hydroxyCBZ) in organs of *J. multidentata* (total weight: 0.5 ± 0.2 g; standard length: 29 ± 2 mm) exposed to 100 µg/L CBZ in water for 48 h under laboratory conditions. Matrix-matched calibration using internal standards was applied (linearity in the range 0.5-1 to 50 µg/L). Limits of detection range were 0.1-30 ng/g dw and recovery between 30-150%. Matrix effects were noticeable, being ion suppression the most important one. When necessary, dilutions were made to diminish this effect. CBZ bioconcentration was observed in the 5 organs of exposed fish (max.: 701 ng/g wet weight in brain) as well as 2-hydroxyCBZ (max.: 107 ng/g ww in liver). The active metabolite 10,11-epoxyCBZ was quantified in gills and muscle (max.: 60 ng/g ww). An enzymatic extraction protocol was applied for the analysis of ACh activity by spectrophotometry in brain and muscle of *J. multidentata* exposed 48 h to 0.5, 10 and 100 µg/L CBZ in water. A significant ACh activation was observed in brain of fish exposed at 10 µg/L CBZ. No differences were observed in muscles under the tested conditions. Results demonstrate that CBS can be uptake by fish from polluted water, metabolized and distributed in diverse tissues, affecting ACh activity.

## WE282

### Sub-lethal effects and protein profile alteration caused by the main cocaine metabolite (benzoylecgonine) in a freshwater biological model

A. Binelli, University of Milan / Department of Biosciences; M. Parolini, University of Milan / Biology; A. Pedriali; i. marisa, Biology; M. Fedorova, R. Hoffmann, Universität Leipzig; D. Sheehan, University College Cork; S. Magni, C. Riva, University of Milan

Illicit drugs represent not only a great social problem, but are also considered a new environmental problem because their use and, often, abuse release large amounts of parent compounds, and especially their metabolites, into freshwaters. One of the most commonly used drugs is cocaine, which is the second most prevalent drug in Europe (accounting for almost 30% of all cocaine users worldwide). Cocaine is rapidly metabolised in humans to benzoylecgonine (35–54%), ecgonine methyl ester (32–49%) and norcocaine (5%), which are eliminated in the urine and are only partially removed by wastewater treatment plants (WWTPs). Because no studies have previously been carried out to evaluate the possible risks due to cocaine and its metabolites in non-target organisms, we applied a multi-disciplinary approach to investigate the possible environmental risk related to benzoylecgonine (BE). Thus, the aim of this study was to investigate sub-lethal effects and the protein pattern alteration induced by BE on the freshwater bivalve zebra mussel (*Dreissena polymorpha*). Mussels were exposed under semi-static conditions for 14 days to two environmentally relevant BE concentrations (0.5 µg/L and 1 µg/L) and induced adverse effects were evaluated through the application of a suite of ten different biomarkers. We applied on bivalve hemocytes the single cell gel electrophoresis (SCGE) assay, the DNA diffusion assay and the micronucleus test (MN test) to investigate DNA injuries, while the neutral red retention assay (NRTA) was used to assess BE cytotoxicity. Catalase (CAT), superoxide dismutase (SOD), glutathione peroxidase (GPx) and glutathione S-transferase (GST) activities, as well as the lipid peroxidation (LPO) and protein carbonyl content (PCC), were measured as oxidative stress indices in zebra mussel homogenates. Moreover, we carried out the redox proteomic approach to evaluate the effect of oxidative stress potentially caused by BE on protein thiols and carbonyl groups in mussel gills. Finally, we analysed the protein expression profile in the gills of Zebra mussels through 2-DE and mass spectrometry analysis (RP-UPLC ESI-LTQ-Orbitrap). This reports presents the main results obtained by this multidisciplinary approach in order to evaluate the environmental risk due to this new pollutant in a non-target organism.

## WE283

### Evaluation of fipronil toxicity to the freshwater midge *Chironomus riparius*: linking molecular-level endpoints to organism level effects

H.R. Monteiro, University of Aveiro / Biology; J.L. Pestana, CESAM & University of Aveiro / Department of Biology and CESAM; S.C. Novais, A. Augusto, Polytechnic Institute of Leiria / ESTM and GIRM; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; B. Devreese, Ghent University / Unit for Structural Biology Laboratory for Protein Biochemistry and Biomolecular Engineering LProBE; M.F. Lemos, Instituto Politécnico de Leiria / Dept Biology Larval stages of nonbiting midges (Chironomidae, Diptera) can be found in almost any freshwater ecosystem. Due to its ubiquitous presence and its ecological relevance, *Chironomus riparius* is commonly used for toxicity testing and risk assessment of freshwater contaminants. Freshwater systems close to agricultural fields are subjected to frequent inputs of chemicals either by spray drift, runoff or leaching events. These inputs often contain sub-lethal and lethal concentrations of

several insecticides, affecting non-target species and with possible adverse effects to ecosystem functioning. Among these insecticides, fipronil is a phenylpyrazole compound that has been replacing organophosphates and organochlorides in agricultural areas since the restrictions on their use. Fipronil acts on the central nervous system of insects by interfering with GABA-gated chloride and GluCl channels, causing an impairment of the regular inhibition of nerve impulses that ultimately result in paralysis and death. In this study, 8-day old *C. riparius* larvae (third instar) were exposed to fipronil-contaminated waters. To evaluate the toxicity of fipronil to midges, survival and sublethal responses such as total emergence, development time and adult body size were used as endpoints. In order to better understand and identify mechanisms of action of fipronil, molecular approaches such as enzymatic biomarkers, protein expression and fatty acid profiling were also used with Chironomid larvae. Exposure to fipronil significantly reduced emergence (LOEC of 0.08 µg L<sup>-1</sup>) and affected viability of the adult midges at concentrations as low as 0.02 µg L<sup>-1</sup>. The development time of exposed female midges was also significantly delayed. Adult body size, which is directly linked to the flying performance and fecundity of midges, was also affected by exposure to fipronil and we observed that emerged adults from fipronil treatments were significantly smaller than midges from control treatments. A comparison between exposed and non-exposed larvae revealed increased and decreased levels of proteins, protein activities and fatty acids. This up and down-regulation may uncover potential mechanisms of action that lead to indirect effects of fipronil, thus providing a molecular interpretation of the effects observed at the organism level.

## WE284

### Toxicity of two antifouling biocides, Irgarol 1051 and diuron, on two marine phytoplankton species

N. Coquillé, IRSTEA Bordeaux Ifremer Nantes EPOC (LPTC); V. Dupraz, IFREMER; S. Stachowski-Haberkorn, IFREMER / BIOGEOCHIMIE ECOTOXICOLOGIE; D. Ménard, R. Sussarellu, L. Haugaraeu, IFREMER Irgarol 1051 and diuron are two booster biocides commonly used in antifouling paints. They target directly the photosystem II by inhibiting the electron transfer between Q<sub>A</sub> and Q<sub>B</sub>. As photosystem II structure does not vary much between different plant organisms and algae, numerous unwanted targets can be affected in case of environment contamination. The single and combined effects of these two compounds were investigated towards two marine phytoplankton species, *Chaetoceros calcitrans* (a single “wild” strain WC) and *Tetraselmis suecica* (two strains: “wild” (WT) and diuron-resistant mutant (MT)). The effects on growth, photosynthetic yield, reactive oxygen species presence and intracellular relative lipid content were assessed after a 6-day exposure to a range of concentrations from 0.01 µg.L<sup>-1</sup> to 0.5 µg.L<sup>-1</sup> for irgarol and from 0.5 to 5 µg.L<sup>-1</sup> for diuron. Diuron induced a significant effect at 5 µg.L<sup>-1</sup> for WT and WC, with an increase of their doubling time by 168% (± 20) and 14% (± 2) respectively. DCFH-DA fluorescence related to ROS presence showed an increase by 94% (± 3) compared to the control for WT. The diuron-resistant strain MT showed no significant effect at the end of the 6-day exposure to diuron 5 µg.L<sup>-1</sup>. Micro-algae exposure to 0.5 µg.L<sup>-1</sup> irgarol also showed significant results, as doubling time increased by 54% (± 4) for WC and by 19% (± 2) for WT after a 6-day exposure. Photosynthetic yield decreased by 25% (± 0) for WC and by 17% (± 1) for WT. The mutant strain was greatly inhibited at 0.5 µg.L<sup>-1</sup> irgarol with an increase of 63% (± 2) and 60% (± 8) of doubling time and DCFH-DA fluorescence, respectively. Finally, a 6-day exposure to a mixture of diuron and irgarol was performed, but results are still being acquired. The sequencing of the *psbA* gene of mutant strain is still ongoing. This study demonstrates the high toxicity of these two biocides to marine phytoplankton. It also demonstrates that resistance to diuron does not necessarily enables resistance to another PSII inhibitor. This highlights the need to monitor the fate of these two compounds in the environment, especially for irgarol, since it's still authorized in many European countries.

## WE285

### Ecotoxicity of Ionic Liquids in *Daphnia magna*

E. Sarasa, Universidad San Jorge; L.E. Eraso, Universidad San Jorge / Facultad de ciencias de la salud; E. Perales, Health Science Department; E. Zuriaga, Universidad San Jorge; B. Giner, Facultad ciencias de la salud Most of the volatile organic compounds (COVs) commonly used are considered as dangerous and/or toxic for the environment. A green alternative to these compounds are ionic liquids (ILs), which have been studied as possible substitute in some scientific and industrial applications. These chemicals are organic salts melt at room temperature. Their unique properties, possibilities of combination, low volatility and flammability and insignificant vapour pressure, make them as a strong option to be considered as green solvents.[1,2] Nowadays there is a huge interest about these compounds and their physicochemical properties and possible applications have been widely investigated. However, the ecotoxicology assessment of this type of chemicals is still undergoing. In this study, we have evaluated the acute ecotoxicity of five ionic liquids (1-propylpyridinium tetrafluoroborate, 1-butylpyridinium tetrafluoroborate, 1-butyl-2-methylpyridinium tetrafluoroborate, 1-butyl-3-methylpyridinium tetrafluoroborate and 1-butyl-4-methylpyridinium tetrafluoroborate on daphnids (*Daphnia magna*), using concentration-response test, assessed as the EC<sub>50</sub>. The ILs have been chosen in order to explore the structure-properties relationship. Results indicate that all the studied ILs affected strongly the mobility of *Daphnia magna*.

Concretely, the most toxic chemical was 1-butyl-4-methylpyridinium tetrafluoroborate followed by 1-butyl-2-methylpyridinium tetrafluoroborate, 1-butyl-3-methylpyridinium tetrafluoroborate, 1-butylpyridinium tetrafluoroborate and 1-propylpyridinium tetrafluoroborate, although there were not relevant differences between them. In general, we could conclude that the presence of an extra methyl substituent slightly increased the toxicity. ## WE286

**Adverse effects of [bmim][BF<sub>4</sub>] and [omim][BF<sub>4</sub>] on mussel *Mytilus galloprovincialis*: an integrated approach with the use of stress indices**  
V. Tsarpali, University of Patras / Department of Biology; A. Belavgeni, S. Dailianis, University of Patras / Biology

The present study investigates the effects of two commonly used ILs (1-butyl-3-methylimidazolium tetrafluoroborate/[bmim][BF<sub>4</sub>] and 1-methyl-3-octylimidazolium tetrafluoroborate/[omim][BF<sub>4</sub>]), in terms of their ability to induce lethal and pre-pathological alterations on marine mussel *Mytilus galloprovincialis*. The mortality test (96h), firstly performed, showed higher levels of mortality in [omim][BF<sub>4</sub>]/water-treated (96h LC<sub>50</sub> = 0.516 mg L<sup>-1</sup>) compared to [bmim][BF<sub>4</sub>]/water-treated mussels (96h LC<sub>50</sub> = 134.536 mg L<sup>-1</sup>), while [omim][BF<sub>4</sub>]/acetone-treated mussels showed higher LC<sub>50</sub> values (96h LC<sub>50</sub> = 2.392 mg L<sup>-1</sup>). Furthermore, the estimation of lysosomal membrane integrity (with the use of neutral red retention assay/NRRT) in hemocytes of exposed mussels showed increased levels of lysosomal destabilization in mussels exposed to sub-lethal concentrations of ILs for 4 days. Based to the above results, a battery of stress indices in mussels' hemolymph was estimated. According to the results, [omim][BF<sub>4</sub>]-exposed mussels (both water and/or acetone-treated) showed significant increased levels of superoxide anion and lipid peroxides (in terms of malondialdehyde equivalents), as well as increased levels of DNA damage, even at low concentrations (-1), while in the case of [bmim][BF<sub>4</sub>]-exposed mussels, the obtained results were more mediated. The results of the present study clearly indicate ILs-induced lethal effects, as well as disturbances on different levels of organism function before mortality occurs. Since those ILs constitute a novel class of chemicals, widely used in a range of applications either pure or in mixtures with water and/or conventional solvents, such as acetone, the present study reveals not only their environmental risk but their handling and management as well.

## WE287

**Ecotoxicology study of glycerol-derivatives in *Daphnia magna***

E. Perales, Health Science Department; C.B. García, Universidad San Jorge / Facultad de ciencias de la salud; J.I. García, Universidad de Zaragoza / ISQCH; L.E. Eraso, Universidad San Jorge / Facultad de ciencias de la salud; E. Pires, Universidad de Zaragoza / ISQCH; B. Giner, Facultad ciencias de la salud  
Glycerol is one of the most representative by-product in biodiesel synthesis fabrication and others industrial procedures, like soap manufacture and microbial fermentation<sup>1</sup>. Furthermore, the use of some glycerol derivatives as solvents in different chemical reactions<sup>2</sup> causes it to be considered a very interesting raw material. However, although the reuse of the industrial-waste glycerol is beneficial for the environment, it is needed to characterize glycerol and some derivatives from an ecotoxicological perspective to ensure low environmental risk. The work we present here forms part of a broader project regarding the ecotoxicological characterization, acute and chronic, of green solvents from biomass through a battery of well-stabilised bioassays. The information obtained is studied together and analysed and the goodness of these kinds of solvents is assessed from the point of view of Green Chemistry. In this case, we show the ecotoxic effect of several glycerol derivatives (3-methoxy-1,2-propanediol, 3-ethoxy-1,2-propanediol, 3-n-butoxy-1,2-propanediol, 1,3-di-n-butoxy-2-propanol, 1,3-di-n-butoxy-2-methoxypropane, 1,2,3-tri-n-butoxypropane) in the crustacean *Daphnia magna* by means of the OCDE 202 "Daphnia sp. Acute Immobilisation Test". The chemicals have been selected with the purpose of studying the effect of the length and position of the substituents in a systematic way. The obtained results have been analysed and compared to those obtained in other bioindicators. In general, significant differences in the ecotoxicological behaviour of the chemicals depending on the structure have been found. Toxicity clearly increases if the length of the alkyl chain increases. In this case, an extra substituent in position 2, does not make the toxicity lower than the corresponding analogous. In general, only the chemicals with long alkyl chains can be considered toxic for the environment.<sup>1</sup>

## WE288

**Investigation of the toxic effects of iodoacetic acid on *Caenorhabditis elegans***  
G. Repetto, Univ. Pablo de Olavide / Biología Molecular e Ingeniería Bioquímica; B. Pardo, Instituto Nacional de Toxicología y Ciencias Forenses / Departamento de Sevilla; C. Alvarez-Herrera, M.J. Muñoz, Universidad Pablo de Olavide de Sevilla / Biología Molecular e Ingeniería Bioquímica

Iodoacetic acid has been identified as one of the toxic disinfection byproducts in drinking water after disinfection with chloramines in the presence of iodide. The

formation of iodoacids is linked to the presence of chloramines, a reaction product of chlorine and ammonia in the final stage of the drinking water chlorination process. Iodoacetic acid is considered to be one of the most toxic disinfection byproducts. It can negatively affect mouse embryo development, is a potent cytotoxic agent and can cause mutagenicity in bacteria and genotoxicity in mammalian cells. The aim of this study was to investigate the main toxic effects of iodoacetic acid on *Caenorhabditis elegans*. The percentage of survival animals was used to evaluate lethality of nematodes, the growth of the nematodes, the brood size to evaluate reproduction, the locomotion behavior was assessed by head thrash and body bend and other effects were detected according to the defecation cycle. Iodoacetate induces toxicity by inhibiting the glycolytic enzyme glyceraldehyde-3-phosphate dehydrogenase, which led to hypoglycemia and the generation of reactive oxygen species. The LC50 at 24hr exposure of *Caenorhabditis elegans* was 7 microM iodoacetic acid, but reproduction was severely reduced from 2.5 and behavior was altered from 1 microM iodoacetic acid. Acknowledgements: this work was supported by the grant CTM2012-31344 from the Spanish Ministry of Economy and Competitiveness and the EU FEDER program.

**Ecotoxicity Study of Lactate and Furfural Compounds**

L.E. Eraso, Universidad San Jorge / Facultad de ciencias de la salud; E. Sarasa, Universidad San Jorge; E. Perales, Health Science Department; E. Zuriaga, Universidad San Jorge; B. Giner, Facultad ciencias de la salud

In the last years, new friendly solvents which pollute less than traditional solvents have been developed and studied. Some of these solvents are ionic liquids, solvents from biomass, supercritical fluids, etc. However, in this case we want to focus on solvents from biomass which have been received much attention as renewable organic resources. It is important to highlight solvents from biomass such as lactate, furfural, furfuryl alcohol, terpenes, levulinates, etc. [1,2] In this case, we want to deepen in lactate and furfural families taking into account their ecotoxicological characteristics because these solvents have been considered as green solvents for their physicochemical characteristics. These solvents can be used as paints, gums, dyes, oils, detergents, food additives, cosmetics, in pharmaceuticals, as lubricants, adhesives and precursor of other chemicals, etc.[3] In this study, an ecotoxicological study of lactate and furfural compounds has been obtained. New data about acute ecotoxicity of studied compounds in water have been obtained using *Daphnia magna* (OECD 202) bioassay. A relationship between the structures of chemicals their toxicity can be seen by examining the physicochemical characterizations of the compound. Furthermore, the relationship of the toxicity and hydrophobicity has been investigated [4]; the log EC<sub>50</sub> values of chemicals studied have been plotted against their log P values. ## WE290

**Human exposure to endocrine disruptors by inhalation: contamination characterization of indoor air by chemical and biological analyses**

S. Laborie, UMR METIS; L. Oziol, University of Paris-Sud / UMR CNRS; F. Alliot, EPHE UMR 7619; A. Desportes, EPHE / UMR METIS; E. Moreau-Guigon, M. Chevreuil, EPHE

Humans are exposed to low levels of environmental compounds through several exposure pathways. Many of them are known or presumed endocrine-disrupting compounds (EDCs) that may interact in mixture with other contaminants under environmental exposure conditions. Inhalation represents a chronic and passive exposure route to these contaminants. Moreover, it is assumed that adults spend at least 80% of their lifetime indoors, where the air is often more contaminated than outdoors. In this context, our purpose was to develop robust multi-residue analytical methods to identify and quantify the exposure to a wide range of EDCs in indoor air. In order to characterize the health hazard inherent to this multi-contamination, a two-track approach was carried out, by combination of chemical and biological analyses. Four dwelling places were compared for their indoor air contamination and with outdoor air, during two different seasons: an office, an apartment and a house to study the general population exposure, and a day nursery to consider a sensitive sub-population. The broadest range of contaminants was extracted from the two atmospheric phases (gas and particulate) of indoor and outdoor air. Liquid or gas chromatography-mass spectrometry analyses were developed for the quantification of 71 molecules, known or suspected to be EDCs, both in the two air phases. These compounds belong to several families with contrasted properties: pesticides, dielectrics, flame-retardants, plasticizers, preservatives, synthetic musks, surfactants or compounds from combustion processes. Along with their chemical analysis, the endocrine-disrupting potential of indoor air extracts was performed using *in vitro* bioassays, i.e. two cellular transactivation tests: MELN and PC-DR-LUC cells respectively for estrogenic- and thyroid-disrupting effects assessment. Our data showed the indoor prevalence of

EDCs, and especially in the gas phase. The endocrine-disrupting potential and the contamination by target EDCs of the indoor air extracts were in accordance, except for seasonal variations. This suggests the presence of non-studied EDCs in air extracts or interactive effects between air contaminants. In this context, an effect-directed analysis approach will be carried out on biologically active air extracts. The objective will be to identify the target compounds responsible for the observed biological responses, while integrating interactions effects between contaminants in mixture.

#### WE291

##### **Identifying New or Emerging Risks of Chemicals (NERCs) for the protection of workers, consumers and environment to support policy**

Y. Bruinen de Bruin, RIVM / Industrial Chemicals

Despite existing legislation to prevent or manage the risks of chemical substances, chemical risks continue to emerge on the short or long term. On the one hand, these risks can be the result of new substances, new applications, technological developments or process innovations. On the other hand adverse effects not recognized before might arise from the long-term use of existing substances. Therefore, a project coordinated by RIVM and financed by the Dutch Government was initiated in 2012 to develop a system to identify New or Emerging Risks of Chemicals (NERCs) at an earliest stage. The project aims to link new information on chemical stressors to effects for three protection goals - workers, consumers and the environment. A major difficulty is the causality between exposure and observed effects. Methodologies in finding and prioritizing NERCs for each protection goal will be presented. In addition, measures are suggested to reduce exposure of the selected NERCs in the nearby future. Despite similarities in the methodologies for the identification of NERCs, the complexity and route of exposure of NERCs also resulted in differences in approaches for the three protection goals. The two common crucial features of the developed procedures are (i) using various sources (e.g. scientific literature, news sites, websites, electronic databases, stakeholder networks) for searching information and (ii) the evaluation of information involving international networks of experts to assess the causality between the chemical exposure and the effect.

#### WE292

##### **Assessment of toxic effects of ibuprofen and triclosan on the activated sludge by biomarkers approach**

G. AMARIEI; K. Boltes, University of Alcala / Chemical Engineering; P. LETÓN, Univ. ALCALA

Emerging contaminants present significant research interest due to their frequent detection in wastewater and to their reported toxicological properties. Usually, the toxicological studies of contaminants in water are carried out evaluating the negative effect of each compound individually on standard organisms at classical apical end-points based on the formal approach of dose-response relationships. Reviewing the literature, there are a limited number of publications on the toxicity of emerging pollutants on biological activity of microorganisms forming the activated sludge, and only individual validations have been performed. However, the stress response measured for a non-homogeneous community like activated sludge is often unspecific. The aim of this study was to investigate the potential toxic effects involving oxidative stress of Ibuprofen (IBU) and Triclosan (TCS), individually and in binary combination, on the microflora of activated sludge. For this purposes, were assessed biomarkers including enzymatic activities of catalase (CAT) and glutathione-S-transferase (GST). Activated sludge used comes from a laboratory system. The concentration of IBU and TCS ranged 0.5-8 mg/L and 0.006-0.1 mg/L, respectively. Batch toxicity experiments were performed using OXYGRAPH SYSTEM (Hansatech), for determining the activity of CAT based on the quantification of oxygen production rate. Fluorimetric technique was applied as well, using a FLUOROSKAN ASCENT FL (Thermo) for determining the activity of GST, using monochlorobimane-GSH as substrate. The results showed that ibuprofen induced an increase in the activity of CAT at low doses. However, further increasing in IBU concentration reduced CAT activity and returned to the level in the control. Similar to CAT, GST activity varied in a dose-dependent manner. Triclosan induced a lower increase in the activity of CAT and GST, but no significant changes were observed at all doses following its exposure. There were no regular changes in the enzymatic activities of at the tested dose. The toxicants mixture had similar effects on the CAT and GST activities of IBU during individually assay, with an ease off tendency by the presence of TCS. Our findings can suggest that compared with individually substances, the co-occurrence conditions played a much more weakly role in realistic effect on the activities of antioxidant and detoxifying enzymes, as shown in the notable oxidative status imbalances.

#### WE293

##### **Environmental concentrations of the cocaine metabolite benzoylecgonine induced sublethal toxicity in the development of plants but not in a zebrafish embryo-larval model**

M. Catala Rodriguez, Universidad Rey Juan Carlos / Biology and Geology Physics and Inorganic Chemistry; J.P. García-Camero, Institute of Health Carlos III / National Center for Environmental Health; H. Cortés, Universidad Rey Juan Carlos / Biology and Geology Physics and Inorganic Chemistry; Y. Valcárcel, Universidad Rey Juan Carlos / Department of Preventive Medicine Public Health Immunology

and Medical Microbiology

Several studies have found cocaine and its main active metabolite benzoylecgonine (BE) in the aquatic environment and drinking water derived from their high consumption by humans and the inability of water treatment processes to eliminate it. Only a couple of works have addressed BE ecotoxicology on animals and no data have been published of the ecotoxicity of BE on plants or microalgae. The goal of this publication is to provide information on the toxicity of relevant environmental concentrations of BE during animal and vascular plant development in order to contribute to a better assessment of the risk of this substance for freshwater ecosystems. BE induced alterations in mitochondrial activity and DNA levels of fern spores at environmental concentrations (0.001  $\mu\text{g L}^{-1}$ ), which could disrupt gametophyte germination. However, these concentrations did not seem to alter the morphogenesis, hatching time, heartbeat rate or larval motility in a zebra-fish embryo-larval model. These results agree with the allelopathic role described for alkaloids such as benzoylecgonine and their unspecific interference with plant germination. We conclude that the anthropogenic dispersion of alkaloid allelochemicals may pose a risk for biodiversity and irrigated food production that should be further investigated.

## **Managing nanomaterials in the environment: lessons learnt to date, state of the art and future perspectives (P)**

#### WE294

##### **Determination of toxicity thresholds exerted by AgNPs on earthworm coelomocytes (eleocytes, amoebocytes) through viability and cytotoxicity bioassays combined with flow cytometric analysis**

N. Garcia, UPVEHU / Department of Zoology and Animal Cell Biology; A. Irizar Loibide, Aarhu University (AU) / Department of Bioscience; F. Goñi de Cerio, Gaiker Technology Centre-Zamudio; J. Etchebarria, GAIKER Technological Centre. IK4 Research Alliance.; I. Marigomez, Euskal Herriko Unibertsitatea / Zool Eta AnimZelulen DinamSaila; M. Soto, University of Basque Country / Zoology and Animal Cell Biology Research Centre for Experimental Marine Biology and Biotechnology PIEUPVEHU

The number of applications regarding silver nanoparticles (AgNP) is widely increasing so their release into different environmental compartments such as soils is a matter of concern. However, there is a lack of knowledge on the hazards posed by these materials to soil organisms. Different species of earthworms have been used as sentinel and/or model organisms for soil health assessment due to their early and measurable responses (biomarkers) after exposures to a wide range of pollutants. Those responses can be measured in their immune cells, the coelomocytes. Recently, *in vitro* assays with primary cultures of coelomocytes based on the Neutral Red Uptake (NRU) assay have been developed as cost-effective tools for toxicity assessment of chemicals. However, coelomocytes are a heterogeneous group of cells with two main subpopulations, amoebocytes and eleocytes, which exhibit different sensitivity against pollutants. Therefore, the understanding of the behavior of both cell-types might allow the establishment of accurate toxicity thresholds exerted by AgNP, and to know whether the responsiveness of cell biomarkers can be compromised. Coelomocytes extruded from *E. fetida* were maintained in primary cultures and exposed to PVP-PEI coated Ag-NP (concentrations ranging 0-100 mg/l) and to PVP-PEI coating agent separately (0.0001-10,4 mg/l) for 24 h. The toxicity of AgNPs was assessed by cytotoxicity and viability assays (NRU and Calcein-AM Viability), and flow cytometric analyses were applied to decipher subpopulation dynamics and their sensitivity against AgNP exposure. Internalization and subcellular distribution of AgNPs on coelomocytes was studied by TEM & X-ray microanalysis. PVP-PEI was not cytotoxic while coated AgNPs exerted an initial stress at low doses and severe toxicity at highest concentrations. In addition, a clear difference in the sensitivity of eleocytes and amoebocytes was detected, while eleocytes seemed not to be affected, amoebocytes showed a clear dose-response curve against AgNPs. Hence, AgNPs may have a targeted impact on amoebocytes as a result of preferential accumulation that exerted subsequent subcellular damage. *In vitro* bioassays in combination with flow cytometric analysis succeeded in determining toxicity thresholds exerted by AgNPs in earthworm coelomocytes, being amoebocytes the most sensitive cell-type answering to AgNPs insult. Funded by Basque Gov (Consol Res Groups; IT810-13), UPV/EHU (UFI 11/37), MINECO (Nanosilveromics).

#### WE295

##### **in vitro cytotoxicity of silver nanowires to earthworm coelomocytes caused by surface adsorption**

J. Kwak; Y. An, Konkuk University / Department of Environmental Science

By increasing concern of release of nanomaterials to terrestrial ecosystem, researches on the ecotoxicity of nanomaterials to the earthworms have been steadily reported. In this study, *in vitro* cytotoxicity test were carried out to assess the toxic effects of silver nanowires to earthworm coelomocytes in the cellular level. With flow cytometric analysis of fluorescence after calcein-AM staining, intracellular esterase activities were slightly decreased with increasing exposure concentrations of silver nanowires. The inhibited enzyme activities seem to have low relationship with cellular uptakes due to the negligible changes in the side scattering lights of flow cytometric analysis. However, the increase in the forward scattering lights

were observed in exposure groups. It indicated that adsorption of nanomaterials on the cell surfaces. In addition, images of silver nanowires adsorbed to the earthworm coelomocytes surfaces were observed by scanning electron microscope. These results indicate that intracellular esterase activities could be effected by silver nanowires adsorptions to earthworm coelomocytes surfaces rather than internalization in the *in vitro* exposure. *This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT and future Planning (2014RIA2A1A11050513).*

## WE296

### Effects of nickel nanoparticles in the soil invertebrate *Enchytraeus crypticus*: a full life cycle test

F.C. Santos, Biology CESAM; S.I. Gomes, University of Aveiro / Department of Biology CESAM; J.J. Scott-Fordsmand, Aarhus University / Department of Bioscience Terrestrial Ecology; M. Amorim, Universidade de Aveiro / Department of Biology and CESAM

The potential impact of Ni-nanoparticles (Ni-NPs) in the environment is still poorly understood, in particular in soil organisms. Concerns have been highlighted regarding the long-term effects of nanomaterials (NMs), often not covered in the currently available standard toxicity tests. Also, the effects of NMs on potentially more sensitive life stages (e.g. embryonic development) are not targeted by most standard toxicity tests. The aim of the present study is to investigate the effects of Ni-NPs (in comparison with NiNO<sub>3</sub>) using the soil invertebrate *Enchytraeus crypticus* (Oligochaeta, Enchytraeidae) full life cycle (FLC) test. This approach is a substantial improvement compared to the standard Enchytraeid Reproduction Test (ERT, ISO and OECD guidelines), as it provides more detailed information regarding the whole lifecycle and hence enable an identification of the most sensitive endpoint. In the FLC organisms are exposed from cocoon stage (1-2 days old) to 46 days, and the endpoints include: hatching (11 days); growth (15, 22 days); time-to-maturity (25 days); survival and reproductive output (46 days). Results showed that hatching was the most sensitive parameter for Ni-NPs exposure, indicating effects in the embryo development. When enchytraeids hatch and grow in the presence of Ni-NPs, their reproductive output seemed to be less affected, in comparison with the effects on the standard test where adults are exposed (21 days). This could indicate a response mechanism in terms of number of juveniles produced as a trade-off. Last, the refined information in the FLC, compared to the traditional test, allows for a better refinement of new research questions which enables a mechanistic understanding. **Keywords:** nickel nanoparticles, soil, full life cycle, hatching

## WE297

### The toxicity of particulate (nano and micro scale) and ionic forms of copper to the marine horse mussel (*Modiolus modiolus*)

H.M. Alnashiri, Heriot-Watt University / School of Life Sciences; M.G. Hartl, Heriot-Watt University / Centre for Marine Biodiversity and Biotechnology School of Life Sciences; T.F. Fernandes, Heriot-Watt University / School of Life Sciences

Copper oxide nanoparticles (CuO NPs) are one example of NPs that are used in many applications, such as batteries, semiconductors and inks. The increased usage of CuO NPs will likely result in an increased release into the environment, especially the marine environment. Furthermore, there is a lack of understanding of the toxicity of CuO NPs on environmental species and humans, particularly marine benthic filter feeders where data are particularly lacking. Therefore, the focus of the current study was to assess the genotoxicity (DNA damage) and oxidative stress in a relevant biomarker organism, the horse mussel *Modiolus modiolus*, chosen for its conservation importance and for its tendency to form reefs which support other species. The mussels were exposed to different concentrations (5, 10, 15 and 20 µg L<sup>-1</sup>) of different forms of particulate CuO (NPs, MPs), and copper in the form of a salt (CuSO<sub>4</sub>), along with the control (medium only), for 72 hours. The Comet assay was used to assess DNA damage in the gill cells of the mussels, superoxide dismutase (SOD activity assay) was used to assess oxidative stress. Flow cytometry was used to assess the viability of the cells and the thiobarbituric acid reactive substances (TBARS) assay was used to measure the extent of lipid peroxidation in gill membranes. The results indicated that all forms of copper (particulate nano and micro, and copper salt) have the potential to cause DNA damage in the gill cells of *M. modiolus* in a dose-related manner, at concentrations that can be considered environmentally realistic. Similarly, SOD activity was observed to have increased and cell viability decreased in the cells of *M. modiolus* exposed to all forms of copper, indicating increased oxidative stress. Finally, lipid peroxidation was increased in all exposed mussels. Overall, all forms of copper (nano, micro and salt) can potentially be toxic to *M. modiolus* even at low concentrations, although CuO NPs were found to be the most toxic to *M. modiolus* in all the experiments conducted. **Keywords:** CuO NPs, oxidative stress, DNA damage, *Modiolus modiolus*

## WE298

### Influence of condition specific aging on nanoparticle toxicity - the role of time

S. Lüderwald, Universität Koblenz-Landau / Institute for Environmental Sciences; F. Seitz, Inst. for Environmental Sciences / Institute for Environmental Sciences; R.R. Rosenfeldt, University of Koblenz-Landau, Institute for Environmental Sciences / Institute for Environmental Sciences; R. Schulz, University of

Koblenz-Landau / Institute for Environmental Sciences; M. Bundschuh, Department of Aquatic Sciences and Assessment Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment

Engineered nanoparticles may enter aquatic ecosystems via various pathways such as wastewater treatment plant effluence. Once in the system those particles can undergo surface modifications including, for example, the seemingly unavoidable coating by natural organic matter (NOM). This process alters the ecotoxicological potential of nanoparticles both instantaneously and over time. However, the aging of nanoparticles under different environmental conditions has rarely been considered. In this context, the present study investigates the acute and chronic effects of a model nanoparticle, i.e. titanium dioxide (nTiO<sub>2</sub>, 99.9% anatase, ~100 nm), on *Daphnia magna*, depending on environmental properties. First, 96-h acute toxicity tests were conducted with nTiO<sub>2</sub>, aged for 0, 1, 3 and 6-d in media with varying ionic strengths (MilliQ water (~0 mmol/L) or ASTM-medium (9.25 mmol/L)) as well as in the presence and absence of natural organic matter (±NOM). Second, 21-d chronic experiments with 0 and 3-d in ASTM-medium (±NOM) aged nTiO<sub>2</sub> were carried out. The acute toxicity test with nTiO<sub>2</sub> aged in MilliQ water (±NOM) did not reveal any statistically significant differences among 96-h EC<sub>50</sub>-values (0.56-1.41 mg/L). This may be attributed to a very limited nTiO<sub>2</sub> surface modification during the aging as indicated by the similar initial particle size distributions. In contrast, the 6-d aging of nTiO<sub>2</sub> in ASTM-medium in absence of NOM caused a distinctive particle agglomeration followed by a fourfold decrease in toxicity, compared to 0-d aging. This is also supported by the findings of the chronic experiments with 3-d aged nTiO<sub>2</sub> in ASTM-medium -NOM, which showed relative to 0-d aged nTiO<sub>2</sub> a decreased toxicity up to 100%. In comparison, for ASTM-medium +NOM, the 96-h EC<sub>50</sub> of nTiO<sub>2</sub> toxicity decreased by up to ~50% within the first 3-d of aging, while 6-d of aging decreased the toxicity by ~60%, in relation to 0-d aging. Also the chronic experiments displayed that 3-d aged nTiO<sub>2</sub> in ASTM-medium +NOM caused an increased toxicity relative to 0-d aging. The present study thus suggests that the aging of nTiO<sub>2</sub> in the presence and absence of NOM modifies the toxicity of nTiO<sub>2</sub> in a condition-specific (aquatic surrounding and time dependent) manner, while the underlying mechanisms remain unclear.

## WE299

### Trophic transfer of metal nanomaterials - should we be concerned?

S.R. Tangaa, F.R. Khan, Roskilde University / ENSPAC; H. Selck, Roskilde University / Dept Environmental Social and Spatial Change

Engineered nanomaterials (ENMs) are used in a wide range of products worldwide, such as inks, plastics, consumer products, lubricants, electronics and bioactive coatings. These particles will ultimately end up in the aquatic environment and have been shown to be taken up by a variety of species; however research on potential trophic transfer of ENMs is limited. The first studies on trophic transfer of metal ENMs, were concerned with the transfer of Cd Quantum Dots (QDs) from bacteria to rotifers and from algae to daphnia (Holbrook *et al.*, 2008; Bouldin *et al.*, 2008). Both groups showed that there was a transfer of these particles from the lower food chain level (bacteria, algae) to higher organisms (rotifers, daphnia), even though no biomagnification occurred. Other studies have been conducted with different kind of metal ENMs within both aquatic and terrestrial environments (e.g. Zhu *et al.*, 2010; Judy *et al.*, 2011; Conway *et al.*, 2014) and all have detected a potential transfer of these particles up through the food chain. In addition, all of these studies comment on the same issue – the need for further research. By investigating the current knowledge base regarding the trophic transfer of metal ENMs, an overview of present studies, results, concerns and knowledge gaps within this field will be obtained. A survey of the available literature, including experimental setup, organisms, particle types and end-points will be discussed, and put into a greater context regarding relevant exposure scenarios and environmental realism. Such an overview is essential to better understand the risks associated with ENMs moving between trophic levels. **References:** Holbrook *et al.*, 2008, Nature Nanotechnology, 3, 352-355; Bouldin *et al.*, 2008, ET&C, 27 (9), 1958-1963; Zhu *et al.*, 2010, Chemosphere, 79, 928-933; Judy *et al.*, 2011, ES&T, 45 (2), 776-781; Conway *et al.*, 2014, ES&T, 48, 1517-1524

## WE300

### Modification of nanoparticles to reduce environmental toxicity

B.K. Gaiser, School of Life Sciences; D.J. Brown, Marietta College / Department of Biology and Environmental Sciences; V. Stone, Heriot Watt University; T.F. Fernandes, Heriot-Watt University / School of Life Sciences

The FP7 project NANOMICEX focuses on safety by design to generate nanoparticles useful for the ink and pigment industry containing modifiers to mitigate their risk to humans and the environment. Results from initial acute aquatic OECD studies and attempts to modify the most toxic particles revealed that out of a panel of seven nanoparticles, zinc oxide (ZnO) and hydrophobic quantum dots (CdSe) were the most promising candidates for successful modification, showing both high toxicity and potential for modification with organic ligands. Acute toxicity tests according to OECD protocols were performed using *Daphnia magna*, *Lumbriculus variegatus* and *Pseudokirchneriella subcapitata* as test models, and particle concentrations of up to 100 mg/l were used; for certain particles with low toxicity an EC<sub>50</sub> could not be established in some organisms. Modification of ZnO with a protein coating reduced the EC<sub>50</sub> in *D. magna* and *P. subcapitata* by a factor of 171 in *P. subcapitata* and more than 300 in *D. magna*, while ZnO had not shown toxicity in *L. variegatus* prior to modification. For hydrophobic CdSe, modification

of the particle core with a ZnS shell and a silica-linked sugar reduced the EC<sub>50</sub> in *P. subcapitata* by a factor of 3.15, in *D. magna* by a factor of 125, and in *L. variegatus* by a factor >3. *L. variegatus* locomotive behaviour was also less affected by the new modified CdSe than by hydrophobic CdSe NPs. The biokinetics of unmodified and modified ZnO NPs to *L. variegatus* and sub-lethal effects on oxidative stress in *L. variegatus* and *D. magna* are currently being investigated by assessment of catalase and superoxide dismutase activities in the organisms. In parallel studies, we also found that the modified nanoparticles had reduced cytotoxicity in mammalian hepatic, phagocytic and alveolar cells. These findings suggest that the modifications established in this project may be a step towards safety by design, generating particles which can be produced at a moderate to large scale and employed by industry, with less risk to workers, consumers and the environment.

### WE301

#### **Environmental, health and safety impacts of the use of nanomaterials in the textile finishing industry. ECOTEXNANO project.**

R. Villalba, Leitat Technological Center / Sustainability Unit; N. Fuentes, Leitat Technological Center; M. Escamilla, LEITAT / Sustainability Unit; J. Mota, Leitat Technological Center / Advanced Materials Division; M. Santamaría, ITENE / Chemical Safety Division

In response to competitive challenges, the textile industry in Europe should improve their competitiveness by ceasing mass production and simple fashion products and concentrating instead on higher value-added sustainable products. The use of nanomaterials is gradually increasing daily due to the new properties addressed by the nanotechnology based products. Such rapid proliferation results in a key environmental problem due to the lack of knowledge of their health and environmental impacts and subsequent effects on the ecosystem. Within this scope, the overall aim of ECOTEXNANO project is to improve the environmental performance of best innovative solutions that are emerging with regard to technical textiles that incorporates nanoparticles in the textile finishing industry. The project addresses four textile functionalities: soil release, UV protection, antimicrobial and flame retardant; the most representative nanomaterials that are being used in textile finishing processes by functionality have been selected. Environmental, health and safety impacts are being assessed by carrying out a comprehensive Life Cycle Assessment of the manufacturing operations and Risk Assessment of the selected nanomaterials. The analysis will allow quantifying the environmental impacts of the use of nanomaterials in substitution of bulk substances, and to guarantee that these nanomaterials do not pose risk on workers and environment. Demonstration is being developed into two pilot scale trials (Spain and Italy) in order to provide evidence of best practice in the application of nano-based techniques comparing with the conventional finishing chemicals. The project results will provide the textile finishing industry a user-friendly tool to support the chemical safety assessment of nanomaterials along their life cycle and to bridge knowledge gaps on nanomaterials properties, hazard and exposure. The tool will compare nanotextiles and conventional textile finishing products and quantify the achieved environmental and risks improvement. It will be the basis for further development of a network platform to share data with relevant stakeholders. In addition, an online tutorial will be available in order to support textile companies to quantify the environmental improvement and risk reduction achieved. Based on the results, human health and environmental EU policy such as REACH and CLP Regulation, biocidal products, BREF for textile sector will be analyzed for potential updating.

### WE302

#### **The Effects of Nanoparticles on The Freshwater Microalga *Pseudokirchneriella subcapitata***

F.M. Alqahtani, Heriot-Watt University / School of Life Science; J. Kalman, School of Life Sciences; H. Johnston, Heriot Watt University / Life Sciences; V. Stone, Heriot Watt University; T.F. Fernandes, Heriot-Watt University / School of Life Sciences

This poster reports the results of a study assessing the effects of different nanoparticles on the microalga *Pseudokirchneriella subcapitata*. The increased use of nanoparticles in a wide range of products has led to their potential release into the environment. In this study the microalga *Pseudokirchneriella subcapitata* was exposed to different concentrations of a range of nanoparticles widely used in consumer applications. Algal growth was measured at different time points (0, 24h, 48h, and 72h) using different methods, namely optical density (OD) and fluorescence of the culture, as well as chlorophyll a, after extraction (OECD guideline 201). Results indicate a dose response effect, with increased inhibition observed with increased nanoparticle concentration. A comparison of the different nanoparticles studied will be made in regards to their toxicity to the microalga discussed in the context of their use in realistic scenarios.

### WE303

#### **QSPR models for the prediction of the adsorption of organic molecules on multi walled carbon nanotubes**

E. Papa, Department of Theoretical and Applied Sciences

The investigation and prediction of toxicological and physico-chemical properties of nanoparticles (NPs), as well as of the interaction of organics with NPs surface, is a challenging topic. *In silico* approaches based on quantitative structure-property relationships (QSPR), can be applied to investigate ecotoxicologically relevant properties of NPs. This poster shows some examples of QSPR models generated to

predict the potential adsorption of small organic molecules on the surface Multi Walled Carbon Nanotubes (MWCNTs). The organic chemicals interacting with the surface of the MWCNTs were structurally described by conventional molecular descriptors, which have been calculated by using freely available online software (PaDEL Descriptors). The QSPR models were developed in the software QSARINS by Multiple Linear Regression (MLR - Ordinary Least Squares(OLS) method), and external validation was performed by splitting the available experimental data into training and prediction sets. The All Subset and the Genetic Algorithm Variable Subset Selection procedures were applied to select the modelling structural information from the hundreds of molecular descriptors available in this study. Literature models generated by using Abraham descriptors were compared with the new QSPRs based on conventional descriptors. In particular, an in depth analysis of the applicability domain of the models has shown that the current experimental information used to generate QSPR models, was not sufficient to generate reliable predictions for the potential adsorption of small biomolecules (i.e. hormones) on the surface of MWCNTs. Finally, a robust and externally predictive QSPR regression model was proposed to predict the adsorption of small organics on MWCNTs. This model is a valid alternative to the more complex literature models developed for the same endpoint using Abraham descriptors.

### WE304

#### **Quantitative (Nano)-Structure Activity models for heterogeneous metal oxide nanoparticles**

E. Papa, Department of Theoretical and Applied Sciences; J. Ponti, European Commission, Joint Research Centre, Institute for Health and Consumer Protection; J. Doucet, A. Panaye, R. Brayner, Paris Diderot University / ITODYS

The current use of nanoparticles (NPs) for industrial and pharmacological applications has become a reason of increasing concern due to their possible toxicological activity in humans and other organisms. The lack of experimental information available to describe the structural properties of these new materials, and the lack of *in vivo* or *in vitro* measured activities for large sets of NPs, are among the main problems associated to the development of *in silico* models based on Quantitative (Nano)-Structure Activity Relationships (Q(N)SAR). In this poster we want to show some examples of Q(N)SARs developed to model the biological activity of heterogeneous metal oxide NPs, also highlighting the strengths and weaknesses of the performed approaches. Different datasets of heterogeneous metal oxides NPs structurally characterized by experimentally measured properties, such as surface charge, size, aggregation properties etc... were modelled to predict different responses of biological activity (i.e. cytotoxicity and cell membrane damage). The QSAR models were developed by using several statistical approaches, and taking into account the OECD principles for the development and the validation of QSARs, thus paying particular attention to the evaluation of applicability domains, to the validation of the models, and to the interpretation of the molecular descriptors. The proposed models are promising, however small applicability domain represents one of the main limits associated to these models. This is a direct consequence of the limited dimension of the available experimental data sets. Observations from this study provide additional information on which issues represent limitations and possibilities for the future improvement and application of QSAR-based approaches to NPs. This information is useful to improve application of *in silico* methods to hazard and risk assessment procedures of NPs, and to perform *in silico* screening of NPs.

### WE305

#### **In silico approaches for the prediction of the biological activity of surface-modified nanoparticles**

E. Papa, Department of Theoretical and Applied Sciences; J. Doucet, A. Panaye, Paris Diderot University / ITODYS

Different *in silico* approaches based on quantitative structure activity relationships (QSAR) are currently applied to investigate the potential biological activity of nanoparticles (NPs). In this poster we want to show some examples of models which can be generated to study the effect of changes in the organic coating on cellular interaction phenomena of surface-modified NPs. Different literature datasets were used to model *in vitro* "uptake in" and "association to" cells, of cross-linked iron oxide, gold and silver nanoparticles, with heterogeneous surface modifications. The organic chemicals used to modify the surface of the functionalised NPs were structurally described by conventional molecular descriptors, which were calculated by using freely available online software (PaDEL Descriptors). Structural information on experimentally derived structural descriptors (i.e. NPs size, charge, and aggregation state), as well as on the serum protein corona fingerprint, was additionally available for one of the literature datasets. We applied multivariate analysis to investigate macro-properties of the structural datasets, and this information was useful to perform the subsequent QSAR modelling on the endpoints of interests. Different statistical approaches were used to generate QSAR models. The selection of the best combinations of descriptors was performed by applying the All Subset and of the Genetic Algorithm Variable Subset Selection procedures. The best models were validated for internal robustness and predictivity, and the external validation was performed by splitting the available experimental data into training and prediction sets. A mechanistic interpretation of the modelling descriptors was proposed in order to clarify which structural features have the heaviest influence on the modelled endpoints, and the

applicability domain of the models was quantified and explored to evaluate the reliability of predictions. Finally, the poster will include some preliminary results on the prediction of cellular interactions by using the serum protein corona “fingerprint”.

### WE306

#### **Oxidative stress of Silver nanomaterials to soft- and hard-bodied soil living invertebrates**

L.A. Mendes, Departament of Biology CESAM; M.J. Ribeiro, Biology; V.L. Maria, Biology Department of Aveiro University / Biology CESAM; J.J. Scott-Fordsmand, Aarhus University / Department of Bioscience Terrestrial Ecology; M. Amorim, Universidade de Aveiro / Department of Biology and CESAM

It is known that silver nanomaterials cause toxicity to organisms, possible partly through oxidative stress. In the present we studied the link between oxidative stress and the reproductive effects. We compared the oxidative response between a soft and a hard bodied organism, *Folsomia candida* and *Enchytraeus crypticus*, both standard species, employing exposure to both nano silver and soluble silver salts. To get a comparable mechanism of response scenario the comparison was based on exposure at similar effect concentrations [e.g. EC20,50,80] for the reproductive output and along time (0-10 days). The measured markers were catalase, glutathione reductase and glutathione-S-transferase activities, as well as total glutathione, metallothionein and lipid peroxidation levels. The response mechanisms seem, in general, to be similar in both organisms to each of the silver forms, although the response level differed between the two species. Similar activation pattern of glutathione reductase for either silver form was determined, while metallothionein increased after exposure to AgNP for both species. Differences in responses between species were observed in terms of time of events: for *E. crypticus*, LPO levels and enzyme changes occurred earlier (3 days) than for *F. candida* for AgNO<sub>3</sub> whereas the opposite occurred for AgNP (7 days for *E. crypticus* and 2 days for *F. candida*).

### WE307

#### **Tracing effects of NMs along their life cycle - toxicity in soil (*Enchytraeus crypticus*)**

R.C. Bicho, Universidade de Aveiro / CESAM Department of Biology; M.J. Ribeiro, Biology; J.J. Scott-Fordsmand, Aarhus University / Department of Bioscience Terrestrial Ecology; M. Amorim, Universidade de Aveiro / Department of Biology and CESAM

Nanomaterials (NMs) are used in a vast range of applications and their sustainability requires assessment. In FP7-SUN-Sustainable Nanotechnologies (contract No. 604305) one of the aims is to assess the effects of NMs that are commonly used in products and applications within all of the life cycle. Hence, in the present we assessed the toxicity of a range of NMs at different life cycle stages (pristine, in use, weathered). In this case we focused on the terrestrial compartment and the species *Enchytraeus crypticus* was used. The tested NMs were copper oxide (CuONPs), iron oxide pigment (FeONM), the organic pigment diketopyrrolopyrrole (Irgazin), Carbon NanoTubes (CNT) and Cobalt Tungsten (WCCo). Ecotoxicity tests followed ISO and OECD guidelines for enchytraeid survival and reproduction standardized test (ERT), improved to start with synchronised age organisms. Results showed that CuONPs reduced survival and reproduction in dose related manner being among the most toxic. Comparisons are made between pristine and in use materials for toxicity. Further tests are ongoing including all NM life cycle stages. Acknowledgements : SUN, FP7-NMP-2013-LARGE-7 (No. 604305)

### WE308

#### **Bioaccumulation, subcellular partitioning and metabolism of CdTe quantum dots in the marine mussel *Mytilus galloprovincialis*.**

T.L. Rocha, University of Algarve / CIMA; T. Gomes, Norwegian Institute for Water Research (NIVA); E.G. Durigon, M.J. Bebianno, University of Algarve / CIMA

The increased production and use of Quantum Dot (QDs) in many consumer products and application in nanomedicine raise concerns about their environmental release and impact in aquatic organisms. In this context, metallothioneins (MTs) are metal inducible proteins which participate in the detoxification, storage and metabolism of metals and defense against oxidative stress. These proteins are recognized biomarkers of metal exposure in monitoring environmental pollution, but its functions in invertebrates exposed to engineered nanoparticles (ENPs) remains less known. So, the aim of this study was to investigate the bioaccumulation and subcellular partitioning of QDs and their association with MT induction and oxidative damage in the marine mussel *Mytilus galloprovincialis* exposed to CdTe QDs and its soluble counterpart. Mussels were exposed to 10 µgCd.L<sup>-1</sup> of CdTe QDs and cadmium nitrate for 21 days (accumulation period) and transferred to clean seawater for 50 days (depuration period). Total Cd accumulation and subcellular partitioning (insoluble fraction - IF, high-molecular-weight protein fraction - HMW, low-molecular-weight protein fraction - LMW) of accumulated Cd were determined in mussels' gills and digestive gland. Oxidative damage was evaluated in terms of lipid peroxidation by determining malondialdehyde (MDA) and 4-hydroxyalkenals (4-HNE) concentrations and MT levels were measured by differential pulse polarography.

Both CdTe QDs and soluble Cd accumulated with time in mussels' tissues in a Cd form and tissue dependent manner. Similarly, the percentage of Cd distributed among subcellular fractions was also dependent on the tissue and Cd form. Mussels exposed to QDs and soluble Cd showed higher LPO levels and MT concentrations in their tissues. Cd found in LMW fraction was directly related to MT levels in mussels exposed to both Cd forms, reinforcing the importance of this metalloprotein in Cd metabolism. During the depuration period, mussels showed a similar Cd concentration and MT levels when compared to those at the end of the accumulation period. This indicates that the subcellular partitioning of QDs and their soluble counterpart provides an improvement to predict the metabolism and mode of action of ENPs in marine bivalves and the important role of MTs in the detoxification and elimination of Cd-based QDs and against oxidative stress induced by these ENPs.

### WE309

#### **Sub-lethal toxicity of modified and unmodified nanoparticles in freshwater organisms**

J. Roy, Heriot-Watt University / School of Life Science; B.K. Gaiser, School of Life Sciences; T.F. Fernandes, Heriot-Watt University / School of Life Sciences  
Manufactured nanoparticles are increasingly being used to improve the quality of products and materials. Health and safety of workers is an issue of great concern. Focussing on this issue, the NANOMICEX project (FP7) aims to mitigate risk and control exposure in nanotechnology, particularly for ink and pigment based industries. The research is focused on design and risk assessment of engineered nanoparticles using cost effective surface modifiers with reduced health hazard and increasing the level of safety for workers while retaining properties necessary for their applications. At the start of the project, ecotoxicology tests were performed using the model species *Daphnia magna*, *Lumbriculus variegatus* and *Pseudokirchneriella subcapitata*. Standard OECD protocols were followed for acute toxicity tests. Based on the market information of inks and pigments, ZnO, TiO<sub>2</sub>, Fe<sub>2</sub>O<sub>3</sub>, CoAl<sub>2</sub>O<sub>4</sub>, Ag, CdSe and Al<sub>2</sub>O<sub>3</sub> nanoparticles were tested for toxicity. The highest toxicity was found for Ag, ZnO and hydrophobic CdSe QDs. After successful surface modification of ZnO with a protein coating and CdSe quantum dots with a shell containing ZnS and sugars linked by silica, the modified particles were found to be less toxic than their unmodified counterparts in all test organisms. In this study, further experiments were undertaken to find out whether the reduced toxicity observed also applied to sub-lethal effects such as locomotive behaviour of *L. variegatus* and markers of oxidative stress in *L. variegatus* and *D. magna* tissue, since nanoparticles containing metals are known to cause toxicity by impacting oxidative defences. Organisms were exposed to unmodified and modified ZnO and CdSe QDs, as well as metal ions. While 10 mg/l of CdSe QDs caused a change in *L. variegatus* behaviour, up to 100 mg/l of CdSe-ZnS-Si-Glucose had no effect. *L. variegatus* were also unaffected by either type of ZnO. Exposures and sample collection for catalase (CAT) and superoxide dismutase (SOD) activity after 4 h (*D. magna*) and 2, 4 and 24 h (*L. variegatus*) were also studied. At this point, the modified nanoparticles appear to be safer to use than their unmodified counterparts, and nanoparticle modification with biomolecules could be an important step in making nanotechnology safer and more environmentally friendly. Moreover, these results will provide insight into the mechanism of particle toxicity and its prevention, and can be used to establish structure-activity relationships.

### WE310

#### **Testing the effect of nanomaterials in worms - lessons learned from in vitro and in vivo studies.**

J.J. Scott-Fordsmand, Aarhus University / Department of Bioscience Terrestrial Ecology; P. Irizar, Aarhus University AU / Biosciences; J. mariyadas, Aarhus University, DMU / bioscience; M. Amorim, Universidade de Aveiro / Department of Biology and CESAM

The impact of toxicity of nanomaterials (NMs) on living species is still poorly understood, in particular in soil organisms. This lack of understanding is partly due to technical difficulties in the actual testing, partly due to a lack of understanding the fundamentals of how NMs interact with biological systems. The aim of the present poster is to provide an overview of the experience gained when testing of the possible effect of NMs on the model earthworm species *Eisenia fetida*. In this way the focus is on the commonalities and differences when testing toxicity of NMs compared to testing traditional chemicals. This includes exposure considerations regarding the best spiking approach, exposure assessment requirements, and the optimal experimental design. In relation to the assessment of the biological responses caused by NMs, the focus is how *in vitro* studies can support commonly performed *in vivo* studies when dealing with NMs. *In vivo* studies can for example support the identification of mechanisms of actions and toxicity pathways which providing an insight into the interactions between NMs and organisms. Practical guidance (e.g. most appropriate methods of adding NMs to the media) and a proposed way forward are suggested, referring to the best practices and homogenisation with OECD and other standardisation purposes.

### WE311

#### **Data requirements for creating quantitative relationships between engineered nanomaterial related characteristics and exposure or effect endpoints**

J.T. Quik, RIVM / DMG; D. De Zwart, RIVM / Centre for Sustainability Environment and Health; M. Bakker, RIVM; I. Gosens, RIVM / DMG; H. Marvin,

RIKILT; D. van de Meent, RIVM / DMG

Currently there is data available on different aspects of the risk assessment of engineered nanomaterials (ENMs). However, in the future not all engineered nanomaterials can undergo experimental testing to acquire the data needed for risk assessment. For this reason smart methods for read across from previous measurements or use of quantitative models is needed. At this point there are models for predictive exposure assessment and several effect studies have resulted in the first species sensitivity distributions. In our current study we have reviewed the current literature to indicate the known qualitative and where possible quantitative relationships between engineered nanomaterials and endpoints that are related to exposure assessment or effect assessment. This resulted in a set of characteristics describing ENMs, the suspension matrix and the interaction between the ENMs and the suspension matrix. These ENM related characteristics were grouped in categories of data: ENM Size and shape, ENM Chemical composition, ENM Surface chemistry, Matrix composition and Matrix conditions. Within these categories there are some clear quantitative relationships that lead to Exposure or effect endpoints. The main conclusion is (1) that for almost all endpoints data from each of these categories is needed. (2) In order to further develop quantitative relationships between endpoints and the dependents, specific research is needed which will report data on each of these categories. Ultimately there is a need to have more data available that describe the experimental conditions, this can be done using some of the currently available data systems and tools for reporting experimental data on ENMs.

### WE312

#### **Toxicity of selected nano-objects and their aggregates and agglomerates (NOAA) to freshwater invertebrates**

V. Ricottone, Heriot-Watt University / School of Life Science; T.B. Henry, Heriot-Watt University / School of Life Sciences; V. Stone, Heriot Watt University; T.F. Fernandes, Heriot-Watt University / School of Life Sciences

This research project is funded by the European FP7 project SUN "Sustainable Nanotechnologies" which aims to address the entire lifecycle of nano-objects and their aggregates and agglomerates (NOAA) (from cradle to grave) creating an integrated approach for the long-term sustainability of nanotechnologies through the development of safe processes for production, use and end-of-life processing of nanomaterials and products, as well as methods reducing both adverse effects and exposure to acceptable levels. Aquatic exposure studies were conducted on two model species: the cladoceran *Daphnia magna* and the snail *Lymnaea stagnalis*. The experiments have started assessing the ecotoxicity on the aquatic ecosystem of prioritized pristine engineered NOAA (Org. Pig.-Red254, WC-Co, MWCNTs and CuO) among the 8 different SUN nanomaterials. The initial studies were focused on the evaluation of the acute lethal toxicity of copper oxide NPs to juveniles (7-9 day old) of the pond snail *L. stagnalis* exposed for 96h at 20°C to Cu, either in the form of CuO NPs or as aqueous salt,  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ . LC50 values estimated were, respectively,  $2500 \mu\text{g L}^{-1}$  Cu and  $5.5 \mu\text{g L}^{-1}$  Cu, indicating a greater toxicity on *L. stagnalis* of  $\text{CuSO}_4$  than CuO NPs. Screening tests were conducted for the remaining prioritized nanomaterials using the crustacean *D. magna*, in order to assess the threat these NOAA might pose onto the ecosystem before proceeding with further investigations. Overall results indicate a moderate toxicity for Org. Pig.-Red254 and a much lower toxicity for the other two NOAA, WC-Co NPs, and MWCNTs. Respectively, L(E)C50 immobilization values on *D. magna* for Org. Pig.-Red254, WC-Co NPs are:  $1900 \mu\text{g L}^{-1}$  Org. Pig.-Red254,  $33700 \mu\text{g L}^{-1}$  WC-Co NPs. For MWCNTs, in the range of exposure concentrations was only possible to detect the L(E)C20 with an estimation of  $9600 \mu\text{g L}^{-1}$ . Long-term reproduction tests assessing the impact that these NOAA, their fragmented products (FP) and the weathered fragments products (WFP) may pose, based on Predicted Environment Concentration (PEC) on *L. stagnalis*, are ongoing. Endpoints, such as hatching rate, vitellogenin-like protein and quality of eggs produced by exposed snails will be evaluated.

### WE313

#### **Evolution of nanoparticle-protein corona, learning lessons from quantitative proteomics for nanosafety**

S. Cristobal, Linköping University / Department of CI and Exp Medicine Cell Biology

Nanosafety is today focused on investigating the key elements that could provide the essential and sufficient information to provide safety for people and the environment. One of those key elements is the understanding of the nano-bio-eco interphase. The state-of-art of mass spectrometry could build a bridge to reveal the key features of nanoimpact on the environment, biological fluids or cell content and provide a framework to evaluate the impact of any future nanotechnological innovations. The nanosafety of a nanoparticle (NP) should be studied through its evolution rather than at the stage of newly synthesized entity. The nature of the protein corona (PC) in contact with different biological environments has been extensively reported. Nevertheless, less few studies addressed the evolution of the PC in terms of how the transition from an extra- to intra-cellular environment can modulate its biological identity and physicochemical properties. The objective of this work are: i) to characterize the evolution of PC in the transition through different biological media, in terms of both changes in composition and physicochemical properties, ii) develop methodologies that can define the specific enrichment of the PC surface, and iii) integrate MS-based PC data to develop

nanointeraction tools for nanosafety. The results presented here will contribute to define a systematic characterization of PC, fundamental to understand nano-cellular interactions and establish adequate *in vitro* and *in vivo* models for NP risk assessment. Many studies have addressed the properties and composition of the corona in biological fluids or plasma, but not during the transition from one biological environment to another, tackling the dynamism in the corona across distinct fluids. We expect that our work could serve to unravel how the PC evolves across distinct biological media by knowing its physicochemical properties and identity. This knowledge should help to evaluate and even predict cellular responses to NPs. We proposed that by evaluating the proteins in PC, how protein adsorption changes across different biological media, and how this affects NP physicochemical properties, this knowledge may serve to address the NP-cellular interactions closest as possible to physiological conditions. The results offer new perspectives and improve methodologies to study nano-bio interactions with more complex environments and to develop nanointeraction tools with prediction capability.

### WE314

#### **Uptake, distribution and toxicological effects of two different silver nanomaterials in 3-D *in vitro* fish cultures**

A.N. Jha, Plymouth University / Biological Sciences; T. Vicari, Plymouth University / School of Biological Sciences; M. Baron, School of Biological Sciences; R. Maunder, Plymouth University / Biological Sciences; A. Latorre, University of Nottingham / Nottingham Nanotechnology Nanoscience Centre; G. Rance, A. Khlobystov, University of Nottingham / School of Chemistry

The potential detrimental effect of engineered nanomaterials (NMs) on aquatic ecosystem health has become an increasing concern. Silver NMs in particular have been extensively studied for hazard assessment as they are utilised in a large number of consumer products, or are by-products of industrial processes. Different forms of silver NMs and their associated mechanistic properties have been described and reported in the literature. Whilst evaluating the potential hazards associated with various silver NMs, it emerges that chemical properties and media composition could influence their accumulation and resultant toxic properties. Here we present the results from studies that measured the uptake and distribution of two different types of silver NMs possessing divergent surface chemistries (dodecanethiol and PVP) and solubility properties in 3-D liver spheroids from fish. This *in vitro* spheroid model established in our laboratory has demonstrated better organ-specific functionality than conventional 2-D *in vitro* models. Prior to evaluation of their potential toxicity, characterisation of the NMs were carried out in the culture medium (L-15) with and without serum (10% FBS). These characterisation techniques included transmission electron microscopy (TEM), UV-vis spectroscopy, dynamic and phase analysis light scattering (DLS and PALS respectively). We determined the relative accumulation of these two forms of silver NMs in this *in vitro* model using inductively coupled mass spectrometry (ICP-MS) and electron microscopy studies. Subsequent to bioaccumulation studies, we evaluated the biotransformation activity (EROD) and oxidative stress in terms of glutathione and lipid peroxidation (TBARS). Characterisation studies suggested a change in the surface chemistry and resultant solubility of the materials in the presence of serum, which was common for both the NMs used. This was confirmed by UV-vis spectroscopy which showed the characteristic surface plasmon resonance (SPR) absorbance peak at ~410 nm in both media. Overall, our studies indicate the 3-D spheroid models as an efficient and robust model to study bioaccumulation and potential toxic effects of different forms of engineered NMs.

### WE315

#### **Designing nanomaterials towards a sustainable nanotechnology: and example with polyelectrolyte-surfactant nanomaterials**

I. Lopes, University of Aveiro / CESAM Biology Department; G. Chagas, Federal University of Bahia; S. dos Santos, EMPA Technology Society Lab; C. Duarte, F. Antunes, University of Coimbra; E.M. da Silva, Instituto de Biologia da UFBA / Institute of Biology, Department of Botany; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM

Complexes constituted by polyelectrolytes and oppositely charged surfactants are a class of materials with growing interest due to their importance and applications for gene therapy, drug delivery, care products, among others. As their building principle is based on the conjugation of two different compounds, allows a vast diversity in their design and also in their structural and functional properties. Meeting the aim of the European Union to develop greener nanomaterials, these materials constitute ideal raw material to promote a rational development of polyelectrolyte-surfactant nanomaterials that by maintaining their functional properties will also exert lower adverse effects in the environment. Accordingly, the present work aimed at assessing the ecotoxicity of several polyelectrolyte-surfactant nanomaterials (NM) to aquatic biota. For this, ten variations of sodium polyacrylate/ dodecyltrimethylammonium (NaPA/DoTA) NM

were obtained by changing the number of repeating units (m) of NaPA (NaPA<sub>m</sub>; which was always at a concentration of 10 mM of repeating units), the counterion of the surfactant (bromide-DOTAB or chloride-DOTAC) and the concentration of DOTAC (3, 5 and 7 mM): NaPA<sub>25</sub>10/DoTAC3; NaPA<sub>70</sub>10/DoTAC3; NaPA<sub>2000</sub>10/DoTAB5, NaPA<sub>2000</sub>10/DoTAC3, NaPA<sub>2000</sub>10/DoTAC5; NaPA<sub>2000</sub>10/DoTAC7; NaPA<sub>3000</sub>10/DoTAC3; NaPA<sub>3000</sub>10/DoTAC5; NaPA<sub>3000</sub>10/DoTAC7; and NaPA<sub>6000</sub>10/DoTAC3. The lethal and sublethal toxicity of these NMs was assessed by exposing the bacteria *Vibrio fischeri*, the microalgae *Pseudokirchneriella subcapitata*, and the cladoceran *Daphnia magna* to serial concentrations of each NM. The following endpoints were evaluated: bioluminescence inhibition, growth rate and cumulative mortality, respectively. As well, the physical parameters of hydrodynamic size, index of polydispersity, and zeta potential were measured for the highest concentration tested of each NM. In general, the obtained results showed that the NMs composed of DOTAC at a concentration of 3 mM exerted the lowest toxicity to the three tested species, while those composed of NaPA with 2000 repeating units (NaPA<sub>2000</sub>) were among the most toxic. Therefore, aiming at a greener and sustainable development of nanotechnology, it is suggested that, for this type of NM, complexes formed by DOTAC (with the chloride counterion) at concentrations of 3 mM should be target to be developed.

### WE316

#### Classification of baseline toxicants in fish to replace in vivo testing with reliable QSAR predictions

M. Nendza, Analytisches Laboratorium; M. Müller, A. Wenzel, Fraunhofer-Institute for Molecular Biology and Applied Ecology  
Reliable QSAR predictions are specific by mode of action (MOA) and compounds with different MOA must be predicted with different QSARs. Functional similarity of chemicals combines toxicological knowledge (which toxicity pathways are stimulated in which species under which exposure conditions) with chemical expertise (which parts of the chemical structures and physico-chemical properties are involved in which interactions) to discriminate between baseline and excess toxicants. The objective is to identify as many baseline toxicants as possible as their acute fish toxicity can be predicted with sufficient accuracy from their log *K<sub>ow</sub>* and, hence, their *in vivo* testing may be waived. In contrast, excess toxicants, and chemicals that cannot be reliably classified as baseline toxicants, require further *in silico*, *in vitro* or *in vivo* assessments. Established tools, such as structural alerts, are used to indicate MOAs that are typical causes of excess toxicity. Verhaar classifications are supplemented with additional chemical attributes and physico-chemical property thresholds to cover a larger range of compounds within the baseline toxicity domain. A stepwise approach was developed to first detect potential excess toxicants and then to positively identify true baseline toxicants. Our objective was to identify baseline toxicants (true negatives) in a precautionary way, not ignoring possible excess toxicants (true positives). At the same time, we tolerate a certain fraction of false positives, i.e. baseline toxicants without specific effects that may be tested instead of predicted. Classification statistics show an overall accuracy of 75.5%. The sensitivity is 96.3% and confirms the precautionary approach to avoid false negatives, i.e. only four mild excess toxicants falsely predicted to have baseline effects. The specificity is 70.5% and indicates potential for improvement. The classification of 56.9% of the compounds of the EPA Fathead Minnow Acute Toxicity Database (EPAFHM) as baseline toxicants suggests that, if this is representative of industrial chemicals, more than 50% of acute fish toxicity testing could be replaced with reliable QSAR predictions.

### WE317

#### Oxidative stress toxicity a gateway for the design of safer chemicals using two model fish species: zebrafish and fathead minnow.

J. Corrales, Baylor University / Environmental Science; L.A. Kristofco, Department of Environmental Science Center for Reservoir and Aquatic Systems Research; j. yates, Oregon DEQ / Laboratory; W.B. Steele, Baylor University; M.S. Williams, CSIRO / Department of Chemistry and Geochemistry; M. Mills, University of Washington; E.P. Gallagher, Department of Environmental and Occupational Health Sciences; T. Kavanagh, N. Simcox, University of Washington; L. Shen, Yale University / Center for Green Chemistry and Green Engineering; E. Beach, Yale University; F. Melnikov, Forestry and Environmental Studies; J. Kostal, Toxfix LLC; A. Voutchkova-Kostal, George Washington University / Chemistry; J. Zimmerman, Yale University; P. Anastas, Yale University / Center for Green Chemistry and Green Engineering; B.W. Brooks, Baylor University / Dept of Environmental Science  
Despite lack of experimental health and safety data in over 85% of the approved commercial chemicals in the U.S., little progress has been made in the design of chemicals with reduced hazard to humans and the environment. The fourth Principle of Green Chemistry states that “chemical products should be designed to preserve efficacy of function while minimizing toxicity”. In this project, we employed *in vivo* toxicological data in two model species, zebrafish and fathead minnow, to initially identify compounds that elicit oxidative stress responses, a biochemical imbalance leading to cellular damage and associated with cancer, neurodegenerative diseases, cardiac function, and infection among other diseases. This unique comparative toxicity approach includes both a model used in biomedical studies and a model used in ecotoxicology. The goal of the study was to define relationships between traditional endpoints and oxidative stress responses

following exposure to eight compounds with the objective to build computational models that associate oxidative stress parameters with chemical attributes. Following OECD FET and EPA WET guidelines zebrafish embryos and fathead minnow larvae were exposed for 96 h to bisphenol A, cumene hydroperoxide, dinoseb, hydroquinone, indene, perfluorooctanoic acid, R-carvone, and *tert*-butyl hydroperoxide. Range-finding tests were conducted to determine 96 h LC50 values, and fish were then exposure to LC50, 40% LC50, 20% LC50, 10% LC50, 5% LC50, solvent control, and control. Mortality was recorded daily. At 96 h, larvae were collected in triplicate (each replicate representing a pool of 10 or 15 zebrafish and a pool of 5 fathead minnow) for each oxidative stress endpoint including lipid peroxidation, total glutathione, DNA damage, and mRNA expression of catalase, gstp, hsp70, superoxide dismutase, nqo1, and nrf2. Differential sensitivities were observed between fish models, chemicals, and response variables examined. Ongoing efforts include computational modeling to identify structural alerts and potential sustainable molecular design guidelines for reduced toxicity of industrial chemicals.

### WE318

#### Structure-toxicity relationships for larvicide chemicals evaluated with *Aedes aegypti*

A. DOUCET, Univdrsity Diderot / Chemistry; J. Doucet, Paris Diderot University / ITODYS; J. Devillers, CTIS

Mosquitoes are not only the cause of nuisances by their bites but these dipterans can also transmit numerous diseases leading to millions of death every year. Repeated use of insecticides for mosquito control has fostered the contamination of the ecosystems, undesirable effects on nontarget organisms and an increasing resistance of mosquitoes to insecticides. As a result, there is a critical need to find new, environmentally safe but effective insecticides that address these problems. In this context, an attempt was made to derive structure-toxicity relationship models allowing to predict the larvicidal activity of 1-(2,6-disubstituted benzoyl)-3-phenylureas [1,2] against mosquitoes. Chemicals were geometry-optimized with the AM1 semi-empirical method in HyperChem (Hypercube, Gainesville) and exported to MOPAC. The structures were then introduced into the CODESSA Pro software (<http://www.codessa-pro.com>) to compute about 250 topological, geometrical, and quantum-chemical descriptors. Chemicals were also described by means of autocorrelation vectors encoding lipophilicity, molar refractivity, H-bonding acceptor ability, and H-bonding donor ability. The data set of 206 molecules was randomly split into learning sets and external test sets of 80-20%. Feature selection procedures were used to optimally reduce the number of descriptors. Classification and regression tree (CART), random forest, Kohonen, three-layer perceptron, and radial basis function artificial neural networks, and a support vector machine with linear, polynomial, and radial basis function kernels were tested as statistical tools. From the various modeling exercises, new candidate molecules were proposed to be synthesized and tested. #### Understanding Oxidative Stress Pathways via Nrf2-related pathways and ToxCast data: Designing Chemicals with Minimal Oxidative Stress Potential.

F. Melnikov, Forestry and Environmental Studies; L. Shen, Yale University / Center for Green Chemistry and Green Engineering; L.A. Kristofco, Department of Environmental Science Center for Reservoir and Aquatic Systems Research; K. Mellor, Yale University / Center for Green Chemistry and Green Engineering; E. Beach, J. Zimmerman, Yale University; J. Corrales, Baylor University / Environmental Science; M. Mullins, Baylor University; j. yates, Oregon DEQ / Laboratory; S. Williams, Baylor University; J. Kosal, Sustainability AZ; M. Mills, University of Washington / Department of Environmental and Occupational Health Sciences; T. Kavanagh, University of Washington; A. Voutchkova-Kostal, George Washington University / Chemistry; E.P. Gallagher, Department of Environmental and Occupational Health Sciences; B.W. Brooks, Baylor University / Dept of Environmental Science; P. Anastas, Yale University / Center for Green Chemistry and Green Engineering  
Reactive oxygen Species (ROS) and oxidative stress (OS) are associated with adverse outcomes such as immune suppression, cancer, aging, rheumatoid diseases, cardiovascular disease and Parkinson's and Alzheimer's diseases. OS is associated with an array of structurally diverse chemicals and may proceed by a variety of toxicity pathways. An important element in OS response is the Nuclear factor (erythroid-derived 2)-like 2 (Nrf2) leucine zipper (bZIP) transcription factor. Nrf2 degradation, and localization controls the transcription of many OS-response genes. This analysis aims to map the Nrf2-mediated OS response pathways via the ToxCast database, and related bioassay response patterns to chemical classes. ToxCast phase II contains high throughput toxicity data for 1,865 commercial

chemicals, pesticides, and pharmaceuticals. The effects of these compounds on gene and protein expression in multiple cell lines are evaluated via 700 bioassays. The unprecedented collection of toxicological data is ideal for *in silico* elucidation of toxicity mechanisms and AOPs. We identified all ToxCast assays pertaining to the Nrf2 OS-response pathway and evaluated the relationships between electrochemical parameters and Nrf2 response pathway, as evaluated by ToxCast. Several bZip transcription factors exhibit patterns of expression similar to Nrfw. Furthermore, the activity of chemicals activating multiple bZip factors tends to lie outside the region of general cytotoxicity and burst effects. The patterns of pathway-specific gene expressions observed in ToxCast and the relationship with reactivity and shaper parameters will help unravel the diverse network. The Molecular Design Research Network (MODRN) aims to use the property-effect relationships and advanced modeling and machine learning techniques to create design guidelines for minimizing oxidative stress effects generated by commercial chemicals.

### WE320

#### Comparison of Ready Biodegradation Estimation Methods for Fragrance Materials and Application to Musk

R.S. Boethling, Exposure Assessment Branch US EPA Office of Pollution Prevention and Toxics

Biodegradability is fundamental to the assessment of environmental exposure and risk from organic chemicals. Predictive models can be used to pursue chemical design (green chemistry) objectives, which are most effectively met when models are easy to use and available free of charge. The objective of this work was to evaluate no-cost estimation programs with respect to prediction of ready biodegradability. Fragrance materials, which are structurally diverse and have significant exposure potential, were used for this purpose. Using a database of 222 fragrance compounds with measured ready biodegradability, 10 models were compared on the basis of overall accuracy, sensitivity, specificity, and Matthews correlation coefficient (MCC). The 10 models were VEGA© Non-Interactive Client, START (ToxTree©), Biowin©1–6, and two models based on inductive machine learning. Applicability domain (AD) was also considered. Overall accuracy was ca. 70% and varied little over all models, but sensitivity, specificity and MCC, showed wider variation. Based on MCC, the best models for fragrance compounds were Biowin6, VEGA and Biowin3. VEGA performance was slightly better for the compounds it identified as having “high reliability” predictions (AD index >0.8). However, removing compounds with one and only one quaternary carbon yielded a similar improvement in predictivity for VEGA and Biowin3/6, but with a smaller penalty in reduced coverage. Results from the models were then used to compare musks across the various structural classes and make inferences about their environmental attributes.

### WE321

#### Substitution of long chain fluorinated copolymers for durable water repellent (DWR) textile modification

S. Schellenberger, Department of Applied Environmental Science ITM; H. Andersson, IVL Swedish Environmental Research Institute Ltd / Department of Chemical and Biological Engineering; I. van der Veen, VU University Amsterdam / Institute for Environmental Studies

Fabric's repellency against polar and non-polar liquids while maintaining breathability is a key functionality in modern textiles. Durable water repellent (DWR) polymers can provide these properties and are therefore produced in high tonnages. Despite differences in polymer architecture that mainly depend on end-uses in textiles, all state of the art DWR polymers have hydrophobic side chains linked to a polymer backbone. These non-polar side chains are based on hydrocarbons, silicones or perfluorinated (PF) moieties and need to be closely packed and orientated towards the fiber surface to achieve an “umbrella-like” repellent effect. Textiles treated with these polymers however might be a source of leaching chemicals caused by degradation of the polymeric (non-fluorinated) backbone or the release of impurities (from production) during the life cycle of textiles. Considering worst case scenarios, degradation can result in persistent contaminants which have been found in textiles already. The phase-out of persistent, bioaccumulative and toxic long chain PF raw materials that were used for very effective DWRs in the past resulted in the development of alternatives based on short chain fluorocarbons (C6 and C4). Although these side chain fluorinated polymers can be considered less toxic and less bioaccumulative, their potential to form mobile and persistent contaminants is not fully understood. Other “ecofriendly” DWR technologies based on silicones or novel star-shaped hydrocarbons (dendrimers) have unclear degradation pathways as well. This lack of reliable data makes a corresponding risk assessment impossible. The aim of the interdisciplinary collaboration SUPFES (<http://www.supfes.eu/>) is to help industry in finding alternatives that can replace long-chain fluorocarbons in textiles with environmentally more benign alternatives. Within the project a unique consortium of scientific and industrial partners collaborate to make sure that functionality and environmental impact can be balanced in the design of future DWR products.

### WE322

#### Aquatic toxicity of biofuels - Using ecotoxicological methods for sustainable biofuel development

S. Heger, Institute for Environmental Research, RWTH / Institute for

Environmental Research; K. Bluhm, Institut für Environm. Research, RWTH Aachen Univ. / Institute for Environmental Research; N. Anders, RWTH Aachen University / Enzyme Process Technology; A. Gergs, RWTH Aachen University / Department of Environmental Social and Spatial Change; T. Seiler, RWTH Aachen University / Ecosystem Analysis; A. Schaeffer, H. Hollert, RWTH Aachen University / Institute for Environmental Research

The increasing global demand for energy, e.g., for the fossil fuel-dominated transport sector requires the development of alternative energy sources. Due to declining production capacities and environmental concerns of fossil fuels, such as emissions of greenhouse gases, governmental support for the development of renewable energy sources, such as biomass-derived fuels, increased considerably. A rise in biofuel production and consumption increases the risk of a release into the environment. The lack of ecotoxicological data on biofuels impedes a sufficient assessment of their environmental hazard potentials. Ecotoxicological biotests can be applied in a prospective assessment of the hazard potential for aquatic ecosystems and allow an identification of the most environmentally friendly biofuel even at a very early stage of the development. This study focused on the investigation of one potential biomass-derived fuel candidate, 2-methyltetrahydrofuran (2-MTHF). The ecotoxicological investigation was conducted by means of acute and chronic *Daphnia magna* biotests according to OECD 202 and OECD 211 adapted to the testing of biofuels, as well as a *Daphnia magna* population assay. We used a toxicokinetic-toxicodynamic (TKTD) model to describe the process leading to a toxic effect and subsequently integrated this model into an individual-based population model. This allows for the extrapolation of population level effects from individual-toxicity testing. The TKTD model is deemed suitable to describe effects resulting from time-variable exposure of the volatile substance. Results from ecotoxicological biotests were used to inform the process-based effect model. Model predictions at the population level were tested along independent population data. This evaluation reveals that the methods applied can be used in a sustainable biofuel development to assess the effects on a population level. However, testing of further potential biofuels has to be conducted. Acknowledgement: This work was performed as part of the Research Cluster “Tailor-made fuels from biomass”, which is funded by the Excellence Initiative by the German federal and state governments to promote science and research at German universities.

## Challenges of regional and global modelling nitrogen and phosphorus in agriculture supply chains (P)

### WE323

#### Macroalgae production and biorefining in Denmark - a life cycle assessment

M. Seghetta, Department of Environmental Science; S. Bastianoni, University of Siena; M. Thomsen, Nationale Environmental Research Institute (NERI), Aarhus University

Macroalgae is a key biomass for the future development of a biobased society. A model of the brown algae *Saccharina latissima* is here utilized as feedstock for a biorefinery system which produces bioethanol, proteins and fertilizers. A Life Cycle Assessment was conducted from cradle to grave; i.e. from cultivation and harvest of *Saccharina latissima* in Limfjorden in the North of Jutland in Denmark, to the use and disposal of the products. The system boundary includes transport and stepwise bioconversion into the above mentioned bioproducts, using system expansion to take into account ecosystem services delivered by the system. The analysis shows that the productivity of the macroalgae dramatically affects the environmental sustainability of the biorefinery system quantified by the impact categories: Climate Change, Marine Eutrophication and Marine Ecotoxicity. Results of the study reveal the use of macroalgae as instrument for reduction of marine eutrophication by P and N fixation when nutrients are then applied in agricultural soil. Carbon and nitrogen flow within the system boundary are quantified and described showing an increase in the soil carbon stock corresponding to a net reduction of CO<sub>2</sub> in the atmosphere.

### WE324

#### Modelling the nitrogen balance of tropical perennial crops: state of the art and challenges for oil palm plantations

L. Pardon, UPR Systèmes de pérennes; C. Bessou, CIRAD / UPR Systèmes de pérennes; P. Nelson, James Cook University / Centre for Tropical Environmental and Sustainability Science; J. Caliman, SMARTRI; R. Marichal, B. Dubos, J. Ollivier, CIRAD / UPR Systèmes de pérennes; B. Gabrielle, AgroParisTech

While a number of models exist to estimate nitrogen (N) losses from agricultural fields, they mostly pertain to temperate climate conditions and annual crops. Few models are available for tropical crops [1], [2], and even fewer for perennial crops [3], [4]. The lack of robust N-flux inventories is particularly critical for LCA of perennial and tropical crops. Oil palm is the most rapidly expanding tropical perennial crop, which raises environmental concerns. Beside land-use change and peatland, oil palm agricultural production impacts the environment mainly through the use of synthetic fertilisers, notably nitrogen [5], [6]. The latter is associated with pollution risks of ground and surface water, and emissions of greenhouse gases. Accurate estimation of N losses is critical to assess the environmental impacts of palm plantations. In this study, we reviewed currently-available models for oil palm cultivation, and appraised their capacity to assess the N balances of oil palm

agro-ecosystems. We identified various operational and process-based models that could be applied to oil palm, although most of them were not specifically adapted for tropical perennial crops. To our knowledge, APSIM is the only available process-based model of oil palm cultivation that includes N losses [7], but the accuracy of its N loss estimates was untested. Other means of assessment were based on statistical models [8]–[10] or other approaches [11]–[13]. Nitrogen balance assessments have shown important uncertainties (Figure). Estimates of  $N_2O$  and  $NO_3^-$  rely on very uncertain and sensitive parameters, such as the clay content for instance with the SQCB- $NO_3$  model [13]. These uncertainties are due to a lack of understanding of processes. In particular, it is difficult to study and understand N dynamics over the whole lifespan of oil palm crops (20–25 years) and to account for varying agricultural practices. Adequate data to characterise various cropping systems is often lacking. Further research is required to develop a procedure that provides a robust assessment of the environmental impact of N management in oil palm cultivation. Particularly, this procedure should have the capacity to account for a range of soils, climates, and management practices over the whole cycle. One track to be pursued is the development of an agro-ecological indicator based on Indigo concept [14], [15]. Such an indicator could help to reduce uncertainties in LCA of tropical perennial crops.

### WE325

#### **Quantifying within-farm nitrogen and phosphorus efficiency in grazing-based dairy production systems**

C. Gourley, S. Aarons, Department of Environment and primary Industries / Soil Science; R. Eckard, The University of Melbourne / Faculty of Veterinary and Agricultural Sciences

The ongoing trend for increased intensification is occurring in grazing-based, as well as confinement-based dairy farms, worldwide. Grazing-based dairy farms are increasingly reliant on imported feed and fertiliser, with consequent greater nitrogen (N) and phosphorus (P) flows, transformations and losses, and a decreasing dependence on N inputs from  $N_2$  fixation by pasture legumes. While it is important to understand how much N and P is imported and subsequently removed in product on dairy farms, the ability to quantify within-farm flows and transformations, as well as the spatial and temporal distribution of N and P, is essential to identify opportunities for improved management. The purpose of this paper is to outline key components of N and P flows and transformations within grazing-based dairy operations, and propose simple metrics which can be used to quantify N and P use efficiencies and manure management practices, using readily collected information from dairy farms. The linking of farm-gate balances with internal N and P cycling processes provides opportunities for targeted improvements in N and P capture and recycling by farmers, and reducing losses of N and P from grazed dairy systems. In particular, this should include: (i) quantifying key nutrient inputs, outputs and stores (i.e. feed, manure) and nutrient balances and efficiencies at a simple (farm-gate) level, (ii) quantifying grazing animal N and P intakes and feed N and P use efficiencies, at least within each season, (iii) quantifying N and P distribution and loading rates at a paddock management scale, including inputs and outputs such as fertiliser applications, forage removal, and importantly grazing animal excreted N and P, and (iv) quantifying the amount and proportion of excreta N and P deposited in unproductive areas which go uncollected, as well as the amount and proportion of excreta N and P collected and redistributed. Such information from suitably comparable farms, can be used to benchmark farms across a range of indices and target farm management improvements. These data targeting within farm spatial and temporal variability need to be factored into LCA studies conducted on grazing based dairy farm systems to more effectively describe the effectiveness of N and P recycling and loss.

### WE326

#### **Prospective LCA for the implementation of an innovating technology recovering nutrients from urine**

E. Igos, E. Benetto, CRP Henri Tudor / Resource Centre for Environmental Technologies CRTE

The risk of phosphorous depletion and of ore quality decrease in the coming future and the increased energy requirements for nitrogen production make urine, where these compounds are highly concentrated, an interesting resource and call for efficient nutrients recovery process. The ValuefromUrine project (FP7 funding) aims at developing a new urine treatment technology based on an energy-efficient bio-electrochemical system. Life Cycle Assessment (LCA) is used to evaluate the overall environmental impacts and benefits of the technology, including its infrastructures and operation, the sewer network where treated urine is mixed with wastewater from other sources and the effects on wastewater treatment plants. The performance of the technology is expected to evolve during the project duration, from the lab tests to a prototype demonstrating its functioning. This emerging technology could be even implemented at larger scale in the market. As a result, life cycle inventory data can be largely affected by these scale changes, both at the

foreground and background levels, and by technology evolution in the supply chain. The intended approach to tackle this issue is the definition of prospective scenarios based on Formative Scenario Analysis (FSA). First, the system is modelled to calculate the inventory data based on parameters, which can be either fixed (e.g. chemical properties) or variable (e.g. urine flow); and related to design choices (e.g. size of the cell components) or uncontrolled by the operator (urine composition). They constitute the technological impact variables (system element influencing the system behaviour), which are then completed by socio-economic impact variables for the FSA. The relations and effects between impact variables are assessed in an impact matrix to identify the key variables. The future state of each key variable is estimated (including uncertainty distributions whenever possible) according to three scenarios: low, medium and large deployment of the technology (e.g. the more the technology is deployed, the larger is the scale, the more efficient it should be). Inventory data can finally be modelled for the different scenarios, allowing the calculation of the life cycle environmental impacts. The latter are represented through uncertainty distributions for the different deployment scenarios and are compared to the scenario without the technology (urine is directly sent to sewer network without pre-treatment).

### WE327

#### **Energy Recovery from wastewater Treatment Plants in Scotland: A Life cycle Analysis Approach**

N. Amponsah; M. Trolldborg, I. Aalders, M. Nijnik, R. Hough, The James Hutton Institute

Waste streams with calorific or resource value exist across all sectors of industry. Currently, many of these streams go to sewer or landfill. There is a vast potential to use such waste streams for renewable energy generation, especially within the water industry. The entire UK Water Industry uses a total of 7,703 GWh/year in electricity whilst Scottish Water currently consumes around 450 GWh/year of electricity. Energy used on clean water production is predicted to decrease in response to leakage and demand reduction, whilst wastewater treatment is likely to show a significant increase due to water quality drivers. Energy recovery strategies could help offset the electricity consumption of the wastewater sector and represent possible areas for sustainable energy policy implementation. In Scotland, many diverse strategies are in place to improve the quality of wastewater treatment, but unfortunately the more advanced the treatment, usually the more energy is required in order to produce better effluent quality. This necessitates a robust energy reduction strategy for the sector, but attaining the required level of water quality and energy savings can be associated with other environmental costs such as emissions from energy production and increase in runoff from sludge application to land. The goal of this study is to investigate both upstream and downstream opportunities for reducing or offsetting energy demand and report on potential energy savings and recovery from wastewater treatment plants in Scotland with its associated costs. Preliminary investigations suggest that the application of sludge to derelict lands for dedicated energy crops production, which as biogas can generate electricity and heat is a potential route for energy recovery. The project uses data from surveys of treatment plants, from site visits to selected facilities, from equipment suppliers, and from published technical literature to analyse the potential for energy recovery. Life Cycle Assessment (LCA) has been the analytical tool used to evaluate environmental loadings. Initial results from the analysis of the selected systems will be presented and analytic issues will be discussed, including an approach to derive budgets of water and energy inputs for water and waste processing, P stocks and flows. The project will be extended to evaluate implications of projections of population, energy and water demand for future energy costs associated with water supply and treatment.

### WE328

#### **From waste to product: a paradigm shift in Life Cycle Assessment applied to wastewater sewage sludge**

M. Pradel, Irstea Clermont Ferrand / Ecotechnologies; L. Aissani; J. Villot, Ecole des mines de Saint-Etienne - Institut Fayol / UMR CNRS EVS; J. Baudez, Irstea / TSCf research unit; V. Laforest, Ecole des mines de Saint-Etienne - Institut Fayol / UMR CNRS EVS

Since the last 20 years, wastewater treatment plants have become more effective in releasing a good quality water in the ecosystem due to stringent European directives aiming at maintaining and improving the aquatic environment (Directive 91/271/EEC, Directive 2000/60/EC). As a consequence, huge amount of wastewater sewage sludge are produced each year. This sludge is currently considered as a waste but new industrial practices and European regulation (End-of-Waste directive) are ongoing to consider sludge as a valuable product. In Life Cycle Assessment (LCA), boundaries are well drawn up between LCA of products and LCA of waste management. Indeed, LCA of products takes into consideration the whole product life cycle from the raw material extraction up to the product end of life with a functional unit defined in terms of system's output (i.e. the product). LCA of waste management considers one or several wastes entering the system from the moment it becomes a waste by losing value up to the moment it regains value or leaves the waste management system as an emission. Specificities of this type of LCA are twofold (1) a functional unit defined as a system's input (the waste to be treated) and (2) the assumption that the waste is free of any environmental load when entering the system, assumption often known as the "zero burden approach". So there is an important gap between the two types of LCA. If

the sludge is considered as a product and no more as a waste, what are the consequences for the LCA performing? Indeed, such a paradigm shift will affect the way to do LCA in the wastewater field. Several methodological questions arise as the wastewater treatment plant will provide several coproducts: the treated water and the sludge. How to allocate the impacts between these two coproducts? Which allocation factors choose to affect an environmental load to the sludge? As a consequence, such methodological developments will enable stakeholders and water companies to highlight (i) the environmental interest to produce renewable energy resources (such as sludge-based biomethane) compared to non-renewable energy resources (such as fossil methane) or sludge-based fertilisers compared to mineral ones, (ii) the impact of water treatment on the environmental load affected to the sludge and so improve the whole environmental impact of the wastewater treatment plant. This paper aims to present the methodological aspects faced by LCA when dealing with this paradigm shift.

### WE329

#### **Environmental implications in the substitution of non-renewable materials by renewable materials through their entire life-cycle: a case study of cork as thermal insulation in building sector**

J.S. Pérez, Universitat Autònoma de Barcelona; J. Boschmonart-Rives, X. Gabarrell, Universitat Autònoma de Barcelona  
Widespread environmental strategy of reducing the environmental impact is to minimize the use of non-renewable materials which involve important impacts to the environment at different stages of the life cycle. Generally the most important impacts of this type of materials are generated in the extraction and processing of raw materials and their processing in their end of life. However there are other phases of the life cycle, such as transport, which become important when the materials are geographically very concentrated and have a global market: e.g. aluminum or copper among others. The replacement of non-renewable materials by renewable materials implies a very important decreasing in the most life cycle phases. Nevertheless many natural materials, widely used, also have a high geographic concentration and the environmental implications of their distribution are highlighted. This is the case of cork, which concentrates its production is concentrated in the coastal regions of the western Mediterranean basin, mainly in the Iberian Peninsula, where 80% of its production is concentrated. The cork production occurs in rural areas, encouraging the establishment of new enterprises and the consequent employment opportunities; implying the economic development of these traditionally depressed areas. Cork has outstanding properties as thermal and acoustic insulation and good resistance to degradation by moisture. Currently, due to their intrinsic properties, cork is used in the construction industry as insulation, though in a limited way. Therefore, to understand the environmental implications of the widespread use of cork as an insulator in the construction sector, this study presents a comparative analysis with the main materials used as thermal insulation. This study was conducted following the LCA methodology in order to understand the environmental implications of the substitution of non-renewable materials for renewable materials such as cork on the thermal insulation of a building.

### WE330

#### **Life cycle assessment as a decision support tool guiding the development of bio-based products**

C.L. Kämpfer, RWTH Aachen University, Institute for Environmental Research / Department of Ecosystem Analysis; T. Seiler, RWTH Aachen University / Ecosystem Analysis; A. Beger, J. Feldhusen, M. Löwer, RWTH Aachen University / Chair and Institute for Engineering Design; F. Moser, RWTH Aachen University / Structures and Structural Design; J. Prell, RWTH Aachen University / Institute for Biology I; M. Trautz, RWTH Aachen University / Structures and Structural Design; B. Usadel, A. Wormit, RWTH Aachen University / Institute for Biology I; H. Hollert, RWTH Aachen University / Institute for Environmental Research  
Demand for bio-based products substituting environmental harmful components strongly increased in recent years. Within the project "TEPHA – Technical Product Harvesting" the interdisciplinary consortium consisting of ecologists, botanists, mechanical engineers and architects aims at growing near net shape components from renewable resources. In a proof-of-concept study bamboo grown in Germany will be used as an exemplary plant species. In most cases bio-based products have less negative impacts on the environment and human health compared to their conventional equivalents made of, e. g., plastics. But it is not necessarily true that such products are also more sustainable than the conventional when considering the whole life cycle from raw material acquisition to recycling or disposal at the end of the product's life time. In fact due to possible hazardous impacts during plant growth a bio-based product is not per se the most sustainable alternative to a conventional one. Therefore the authors of this contribution aim to develop a framework for a comprehensive life cycle assessment (LCA) which will be exemplarily carried out on bamboo cultivation in Germany. After the investigation of the life cycle inventory the impact assessment will be performed to figure out the most important input and output impacts on the environment and human health. The LCA for the bamboo-derived product will be compared to the conventional one to identify the most environmentally friendly alternative. In case of severe negative impacts during the production of bio-based products these results will act as a trigger to optimize the production process and therefore the product's environmental performance considering its whole life cycle. The proofed

harmlessness of a product via LCA can be used as a basis for consumer communication, in industry as an argument towards regulators as well as a unique selling point when introducing the bio-based product into the market. Within the TEPHA project a database consisting of mechanical, botanical and ecological information will be developed. Upon providing the data from LCA studies together with the technical requirements of mechanical engineering and architecture as well as the properties of plants the most suitable plant species can be easily selected from this database according to the intended use. This will facilitate an effective, reproducible production of sustainable products based on renewable materials.

### WE331

#### **Life cycle assessment of biobased chemical building blocks made from European waste streams**

S. Gros Lambert, University of Liege / LGC Processes and Sustainable Development; A. Leonard, Processes and sustainable development  
Many drivers exist to persuade EU businesses to embrace the opportunities of the circular economy. However, the challenges faced by companies, particularly among SME's, in the drive for resource efficiency include access to funding, knowledge and capability, and ability to implement cost-effective technological solutions. It was these factors that inspired the creation of the ReNEW network. ReNEW, 'Resource innovation Network for European Waste', is a €5 million project funded by the Interreg IVB North West Europe scheme aiming to increase cooperation between research and business endeavors to create value from waste by optimizing novel technologies for extracting materials from waste and their reuse in the supply chain. Moreover, the network is seeking the views of industry through its stakeholder engagement process for future initiatives to stimulate innovation for product development. ReNEW can offer some support to develop locally tailored support for SMEs, and invites interested companies to apply for vouchers to cover 50% of research and innovation needs. Successful applicants will be paired with a research centre that best suits the project proposal in the UK, Ireland, Belgium or Germany. ReNEW also aims to inform local, national and European policy makers, and to share transnational best practice and improve specific support to meet the innovation needs of the waste sector. <http://www.renew-network.eu> Within the frame of this project, several technologies have been developed or optimized by partners to improve the valorization of organic wastes in chemical such as furfural, succinic acid or butanol. These processes include chemical or enzymatic hydrolysis of lignocellulosic biomass, its fermentation and the downstream processing. Life cycle assessments (LCA) of the new waste streams valorization routes are included in the project (WP3A12) in order to evaluate their environmental benefit. The aim of this study is to assess the environmental impacts of production of chemical building blocks from organic wastes (lignocellulosic wastes, dairy wastes, whey,...). On the basis of data collected amongst partners of the ReNEW network, LCA of the different processes on development are realized (lab scale or pilot scale), and the results are compared to the impacts of the usual routes currently used to produce the same components. Data are processed in SimaPro software with Ecoinvent database, and analyzed with the ReCiPe method.

### WE332

#### **LCA-LCC optimization tool for selection of electricity generation technologies in residential buildings**

C. Strazza, university of genoa / DICCA; F. Magrassi, University of Genoa / DICCA; A. Del Borghi, University of Genoa; C. Strazza, University of Genoa, Polytechnic School / DICCA; M. Robba, university of genoa / DICCA  
Reduction of energy consumption and use of energy from renewable sources in the building sector constitute important policy measures needed to reduce EU energy dependency and greenhouse gas (GHG) emissions. The recent 2010/31/EU directive requires all member states to set minimum energy performance requirements for new buildings occupied and owned by public authorities. It also introduces the concept of cost optimality, requesting that minimum energy performance requirements are set "with a view to achieving cost-optimal levels". Member states shall establish a long-term strategy for mobilising investment also for private buildings, where the role for the private sector can be to invest in co-financing at instrument level and project level, to identify and develop projects at regional and local level, and to be creative in facing these premises and perspectives. In response to this stimulation for private sector, the set-up of a simple tool dealing with optimization of economic and environmental performance, that can be used for setting targets and strategies in energy management of residential buildings is here proposed. Life Cycle Assessment (LCA) and Life Cycle Costing (LCC) methodologies are combined for the formulation of a simplified tool that is able to identify the optimal set of electricity generation technologies from two alternative approaches, i.e. minimization of Global Warming Potential (GWP) with overall cost constraint and minimization of overall cost with GWP constraint. Both linear and non-linear optimization procedures are implemented with two alternative objective functions, on the basis of the assessment of installation, operation and maintenance costs and emissions of GHG along the life cycle of a set of various technologies, including different layouts of photovoltaic panels, small wind turbines, different sizes of natural gas micro-turbine (for cogeneration) and energy supply from the grid. In order to guarantee the dynamic alignment with the policy context, a threshold value of renewable share and a threshold value of auto-production share are taken into account as constraints of the model, besides the physical characteristics and limitations of the building and area. An Italian building

is used in order to test the application of the tool for a real case study, with consideration of different prospective scenarios for energy demand, cost of gas and electricity.

### WE333

#### **When economy and environment meet: LCA and cost effectiveness analysis of LED light engine for art-work illumination**

g. benveniste, IREC; J. Lloberas, M. Perálvarez, J. Higuera, Catalonia Institute for Energy ResearchIREC; K.A. Cruz, Rutgers University & UMDNJ / Joint Graduate Program in Toxicology, Department of Biochemistry & Microbiology; J. Carreras, Catalonia Institute for Energy ResearchIREC

This study presents the environmental and economic analysis (Life Cycle Assessment -LCA and economic effectiveness assessment) of a fully-tunable LED based light-engine specifically focused on art-work illumination designed and manufactured in the framework of FP7 HI-LED project. When considering different criteria to boost the public acceptance of new technologies, LCA tool is not bringing enough information to address and orient changes in the use of LED lights and therefore a cost effectiveness study, taking into account either capital and operational costs of the LED luminaire has been performed throughout its lifespan. These two approaches offer additional information on the LED luminaire proposed and complete the technology profile description considering two aspects that may drive the change to adopt these products in day life. As a first step a conventional attributional "cradle to grave" LCA comparative analysis of the LED luminaire was performed comparing this light engine to an equivalent halogen luminaire used for art work lighting. The comparison has allowed the detection of the environmental hotspots of the LED luminaire with respect to an equivalent halogen luminaire. The focuses on the LED engine requirements to illuminate frescos under low responsivity materials to keep the illumination below 200 lx. In this case, the colour perception can be largely influenced by the adaptation level. For this reason, the functional unit chosen responds to light an area of 4 square meters when installed at a height of 2.5 meters and obtaining a light intensity of 1600 lumens during 50000 hours in a wide range of colour temperatures. In order to satisfy the functional unit requirements, an appropriate number of LED and halogen lamps have been defined. The functional unit set the initial parameters to calculate the cost effectiveness of the LED technology, that are completed using the cost of the initial investment, the estimation of the electricity cost and their variation during the operational life of the luminaires, among others, that will enable the assessment of the break-even point for the LED technology. The results from both analyses are focused on improving LED systems design for optimal production, minimum resource consumption and decreasing the payback compared to conventional equivalent halogen luminaire.

### WE334

#### **Illuminating the Sistine Chapel: environmental economic costs accounting for new Solid State Light system**

g. benveniste, IREC; M. Perálvarez, Catalonia Institute for Energy ResearchIREC; K.A. Cruz, Rutgers University & UMDNJ / Joint Graduate Program in Toxicology, Department of Biochemistry & Microbiology; J. Carreras, Catalonia Institute for Energy ResearchIREC

Within the FP7 Led4Art project, a new lighting system based on LED technology has been designed and installed in the Sistine Chapel, at the City of Vatican, of improving its illumination quality. To do so, the new SSL (solid state lighting) system increases the illuminance levels on the frescos, preserves the paintings from heat and undesired radiations and enhances the visualization thanks to the higher CRI (Colour rendering index) provided by selected LEDs. Moreover, the implementation of SSL induces sizeable energy savings compared to the existing incandescent technology (halogen and metal halide). However, even if the advantages of adopting LED technology are out of doubt, regarding the economic figures the bigger picture is not yet completely clear. Little has been told about what would happen when the LED lighting system is applied for artwork and when dealing with economic figures, since the investment cost of SSL system is significantly higher compared to conventional lighting. The study here presented shows the results regarding the calculation of the energy, carbon footprint savings and the total cost of ownership calculations of the SSL installation compared to the old lighting system. The adopted approach is based on the Life Cycle Thinking perspective focusing on the environmental and economic impacts during the operational stage of the life cycle of the lighting systems, considering dynamic figures for the electricity GWP emission factor, prices and cost of the CO<sub>2</sub> emitted accounted as an externality. The assessment of the GHG emissions for both configurations has been done using the GWP LCA indicator. The electricity consumed has been assumed to be the same in the period assessment, while the composition of the average Italian electricity grid mix electricity mix varies throughout the years according to EC projections. To accomplish with the economic analysis, the Life-Cycle Cost-Benefit Analysis (LCCBA) methodology has been adopted, which is a robust second-level method. LCCBA uses a differential cost to give a direct comparison of systems under consideration. As with all second-level methods, the time value of money is considered. In addition, a cost-benefit analysis has been done to measure the social impact of this kind of technology by including the social externalities. Therefore, the Social Return on Investment principle will be applied to measure the extra-financial benefits and costs generated by the SSL technology.

### WE335

#### **From evaluation to design support: a proposal to incorporate social sustainability goals in building design**

I. Cueda, Technical University of Madrid / Department of Construction and Technology in Architecture; J. Neila, Technical University of Madrid / Construction and Technology in Architecture

The research deals with the inclusion of Life Cycle Thinking (LCT) into the design of buildings and search for the identification of goals that architects should pursue to enhance the social performance of buildings. To achieve these aims a proposal on how modify the building design process with a LCT approach, a selection of aspects for the assessment of the sustainability of buildings and its translation into social goals has been made. The assessment of Environmental Life Cycle of products and processes has been used to help reducing the environmental impact. This approach is being very useful when it is applied to processes used to obtain always the same product and this is not the case in building design. Each building is a prototype and that makes more difficult to see how changes in the design process will change the assessment results. This is even more challenging when we refer to social sustainability where there is a double indeterminacy, first the cause-effect chain of the process and second the social impact pathways. Design buildings taking into account the LCT means to take design decisions thinking not only about the first day of the building in use but also about things like: What will happen when technical systems require changes to be updated? Is the building adaptable so that it can change its use without major renovation works? How are we going to deal with the end of life of the building? Is its design in a way that all/some materials/parts/systems could be reused or recycle? In recent years projects and labels defining how sustainability in the construction should be assessed were developed. The results of these works were the basis for the development of these social goals. First a review of the aspects assessed was made. The review allowed identifying the main common aspects. The next stage was the selection of the aspects in accordance with two criteria: the first one is that the aspects are affected by the decisions of the architect and the second one that the requirement, valued throughout the aspect, go beyond the requirements established in the Spanish national regulation about construction works. The design and production of buildings requires an adaptation of the results of LC assessments in order to make them useful for the architects. The use of LCT requires a change in the way architects think about buildings. It is feasible to translate sustainability assessment of buildings into social goals more useful to the architects.

### WE336

#### **Allocation solutions for re-use and recycle flows: a case study of an insulating panel from waste tires recycling**

A. De Luca, Politecnico di Milano; A. Valetti, G. Dotelli, Politecnico di Milano / Chemistry Materials and Chemical Engineering G Natta

Defining system boundaries related to re-use and re-cycle flows is a debated topic in the international LCA community and different allocation solutions have been proposed so far; in particular, in open-loop systems (recycled material from one product system to a different product system) there is much uncertainty about which methodology should be applied in order to quantify possible environmental benefits related to input materials from recycling. Actually, the focus is mainly on two methods: one is suggested by the ISO/TS 14067 Technical Specifications and the other one is defined in the PEF Guide. The aim of this study is to evaluate the influence of the methodology on environmental impacts of an insulating panel totally made of waste tires recycling. The LCA analysis is "from cradle to gate", considering upstream and core modules and according to EN 15084, the European Standard about the sustainability of construction works. SimaPro 8.1 is the software used and the impact assessment is carried out using CML 2001 baseline. When possible, input data were collected on site, otherwise they were provided by the database Ecoinvent 3.0. The functional unit is 1 m<sup>2</sup> of insulation material with a thickness that provides a design thermal resistance of 1 m<sup>2</sup>K/W. The study covers more generally the objective of quantifying the environmental sustainability of production of insulation materials, in order to enrich the database on building materials, useful in the design phase or in case of retrofitting of existing buildings.

### WE337

#### **Life Cycle Analysis used by a glass wool producer**

S. Gerbinet, Université de Liège / Chemical Engineering; V. Briard, Knauf Insulation / Head of Sustainability Products Buildings; S. Gros Lambert, University of Liège / LGC Processes and Sustainable Development; A. Leonard, Processes and sustainable development

The aim of this poster is to present the evolution of the use of LCA by Knauf Insulation, a thermal insulation manufacturer, focusing on its two major products: rock and glass mineral wool. After that, the most recent tool developed will be described. Due to the increasing concern about environment, the use of LCA becomes essential in building sector. Therefore, the first LCA for Knauf Insulation products have been realized in order to respond to market demand. The first LCA were realized by external teams and Knauf Insulation published its first Environmental Product declaration (EPD). After that, Knauf Insulation decided to also use LCA for establishing and monitoring sustainability target reflected in its annual sustainability report. Therefore, the first models owned by Knauf Insulation were developed for some European plants and used in this report but all the plants have not yet been analysed. Nevertheless, Knauf Insulation wants to go one step

further and to use LCA to define and quantify environmental improvement objective for all its plants. For this purpose, two generic models able to realize LCA of all Knauf Insulation plants in Europe have been realized, one by product types (glass and rock). These models are designed to be used for Ecodesign but also for EPD. The model for glass mineral wool is described in the following paragraphs. The model, implemented in GaBi 6, is built in a similar pathway than the production process to allow a good understanding of the results and to simplify data collection. The model is made as generic as possible and includes, for each step, all the raw materials that can be used in one of the factories as well as all the energy sources. Parameters allow to define the amount of each raw material consumed, therefore the model can be adapted to any factory simply by setting these parameters accordingly. Moreover, all elements than can be different from one plant than another can also be specified by parameter, for example, transport distance or energy source. The model can also be adapted to almost all Knauf Insulation products by using parameters where necessary: for example, several products have different binder contents, so a parameter defines the amount of binder. As some materials can be recycled at several stages of the process, special attention has been paid to recycling loops inside the model. The high flexibility of the model allow its used as Eco-Design tool or to realize EPD.

### WE338

#### **LCA of temporary structures: the case study of EXPO 2015 Brazilian pavilion**

A. Arrigoni, M. Zucchini, D. Collatina, A. De Luca, Politecnico di Milano; G. Dotelli, Politecnico di Milano / Chemistry Materials and Chemical Engineering G Natta

Major international events, such as EXPOs and Olympic Games, may have non-negligible impacts on the environment. Most of the structures built for these events have generally a useful service life limited to the duration of the event. Unlike traditional buildings, whose operational phase is very long and by far the most impacting one, construction and dismantling phases become much more relevant in temporary structures. More attention should therefore be paid to the choice of the materials in order to reduce the overall environmental impacts of the structure and in particular to reduce the resource depletion and the waste production. The focus for these particular constructions, as also suggested by the "EXPO Guidelines for Sustainable Solutions", must be the possibility of reusing or recycling the entire structure or the components at the end of the event. To achieve the goal it is essential to act on the design phase of the building. The priority must be to simplify the disassembling phase of the structures and to guarantee a second life of the components. The objective of our study is to assess the sustainability, through the LCA tool, of a temporary structure to support its designing phase. The particular case study involved is the Brazilian pavilion, which will be installed during the forthcoming EXPO 2015 that will be held in Milan from May to October 2015. The aim of the research is thus to evaluate how much the design of the building and the choice of the materials can influence the environmental performances of the structure. Different methodologies for the allocation of the impacts at the end-of-life are compared. Preliminary results confirm the importance of the design phase for this particular sector. The predilection of natural and recycled materials in the construction phase and the prevision of the second life of the components can significantly reduce the impact of the temporary structure. The same approach can be adopted for new low-energy buildings, whose burden is usually shifted from the use phase to the production of the components. The possibility to follow the real flows of all the materials at the end of the useful life of the pavilion will guarantee the availability of primary data that will be used to validate the results obtained. The study can finally be considered as reference for future LCA studies of temporary structure in major international events.

### WE339

#### **A methodology for improving the economic and environmental management of the packaging of drugs: integrating LCA and LCCA**

I. BOSCH-FRIGOLA, Universidad San Jorge; M. Pino, San Jorge University / Facultad ciencias de la salud; F. COCA, Universidad San Jorge

In the second half of the twentieth century, the pharmaceutical industry designed a huge variety of new drugs that needed to be protected, identified and dosed to offer them in perfect conditions to users. To make it possible, the use of different types of containers were needed. During these years, the composition of these containers, weight of the materials and superfluous package were changed as well as the design of primary packaging. From the obtaining of the raw materials to their treatment and disposal as waste, these containers are associated with an environmental impact using the life cycle. As the conventional LCA (Life Cycle Assessment) does not include any cost analysis, which is a major criterion in decision making, LCCA (Life Cycle Costing) tools should be integrated in the environmental study. The aim of this work was to evaluate the cost effectiveness of two primary containers (blister and sachet) of Ibuprofen 600 mg - Cinfa throughout their life cycle integrating the economic variables with a conventional LCA. The pharmaceutical industry, distribution systems, users and authorized waste managers were evaluated and in the same functional unit and system boundaries were selected for environmental and economic approach. The input-output methodology analysis of costs facilitated the integration of LCA and LCCA. Results obtained from this design allow the identification of the associated impacts according to each stage of the life cycle of the studied containers, providing a comparative analysis between both environmental and economic impacts. In addition, this research provides a useful

methodology that improves the economic and environmental management of the primary packaging of drugs.

### WE340

#### **Integration of material and energy performance of buildings: I=M+E**

D. Anink, WE Adviseurs; E. Alsema, Utrecht University; A. Meijer, A. Straub, Delft University of Technology / Faculty of Architecture and the Built Environment; G. Donze, WE Adviseurs

In the Netherlands and other European countries, the introduction of an energy performance requirement in the building regulations has resulted in big improvements in the energy efficiency of new buildings. Now that we are going towards zero energy buildings as the new standard, the role of building materials and embodied energy or CO<sub>2</sub> is become more and more important. However, a broader assessment of the environmental impact of buildings, including the building materials, is not so commonplace yet. Since 2014, it is in the Netherlands obligatory to make also a so-called "material performance" calculation for new building projects (dwellings and offices). This new legal requirement raises the problem however, that for designers, project developers and property managers aiming for a sustainable building, it is difficult to look for optimal solutions because they have work with two separate indicators, one for energy performance and one for material performance. As a matter of fact, energy saving measures will have often a negative effect on the material performance because of the additional materials needed for these measures. This effect is very clear for instance in case of photovoltaic panels. To solve this problem, a new framework has been developed to integrate the materials and energy performance calculations of buildings into a single indicator, based on LCA, taking into account not only the embodied and operational energy, but also other environmental impacts that are usually addressed in LCA. The LCA results of operational energy consumption in the building are calculated and combined with the LCA results of the building materials into a single aggregated impact score:  $I = M + E$ . Several choices and assumptions were made concerning the operational energy consumption to facilitate the integration. The system boundaries of the material and energy performance calculations needed to be aligned, and the allocation of collective energy infrastructure has been addressed. This new evaluation method has been developed and will be tested in practice by a consortium including building owners and construction companies. We will discuss methodological choices involved in this evaluation method and present some practice-based results. With the new integrated environmental performance indicator, it is from now on possible to find optimal solutions for sustainable building from both energy and materials perspective.

### WE341

#### **Combining site-oriented and product-oriented approaches for an enhanced environmental assessment of industrial projects**

P. Larrey-Lassalle, IRSTEA Montpellier; E. Loiseau, UMR ITAP; P.C. Roux, Irstea / UMR ITAP ELSA; D. Salze, Ecole des Mines d'Alès; G. Junqua, Ecole des Mines d'Alès; M. Lopez-Ferber, Ecole des Mines d'Alès; R.K. Rosenbaum, National Research Institute of Science and Technology for Environment and Agriculture - Irstea / UMR ITAP

No single approach can address all of the environmental issues raised by the implementation of industrial projects. Different methods should be used, either individually or in combination, according to the questions to be answered. In this light, the convergence of site-oriented and product-oriented approaches proves to be a challenge for performing a comprehensive environmental assessment of industrial developments. Environmental Impact Assessment (EIA) is a procedural method used to evaluate potential positive and negative environmental impacts of a future project (site-perspective). As EIA is a framework for conducting assessments, the EIA practitioner is free to choose the analytical methods considered most relevant to assess the environmental impacts of a given industrial project. Hence, one of them could be Life Cycle Assessment (LCA). LCA is an analytical tool used to perform the environmental assessment of a product, service or process in order to identify possible improvements throughout its life cycle (product-perspective). Several authors offered comparisons between EIA and LCA and discussed their similarities and differences. Yet, rare are publications inferring what each approach could learn from the other. Identified EIA weaknesses likely to be complemented by LCA are: (i) a limited geographical scope, since EIA addresses only local impacts whereas the standard LCA methods could add a regional or global perspective, (ii) the exclusion of effects related to activities upstream and downstream in the supply chain, whereas a life cycle perspective could identify indirect effects and pollution transfers, and (iii) an incomplete assessment of alternative technologies, that could be well-tackled in product-oriented methods such as LCA. This research proposes an integrated framework for the use of LCA in the EIA procedure. It aims to complement and update earlier work in the field, where a framework was suggested for the integration of different environmental tools (including LCA) in Strategic Environmental Assessment procedure (SEA), which is a meso or macroscopic EIA applied to policies, plans and programs. It will be shown in which steps of the EIA process, for which environmental aspects, to what extent, and for which purpose LCA principles could be applied. Then the remaining bottlenecks and methodological issues that could arise in doing so will be exposed and the areas offering research opportunities for improvement will be discussed.

### WE342

#### Assessing future societies with Life Cycle Perspective

Y. Arushanyan, CESC Centre for Sustainable Communications and Div Environmental strategies research; . Moberg, E. Ekener-Petersen, L. Aguiar Borges, KTH Royal Institute of Technology / CESC Centre for Sustainable Communications and Div Environmental strategies research  
In a joint project researchers at KTH in collaboration with ICT industry and municipality developed five possible future scenarios for Swedish ICT society. The scenarios and their development are used to learn about possible futures and their potential environmental and social impacts, and to provide basis for planning. Life cycle thinking is crucial for the assessment of future scenarios, however the detailed level of LCA is not useful when assessing complex systems, such as a society. Thus, a methodological framework for the environmental and social assessment with a life cycle perspective was developed within the project. Within this development relevant aspects to be assessed and indicators to be used for assessment were defined as well as a process for assessment. The process of the methodological framework development consisted of iterative steps: a literature overview, discussions within the interdisciplinary assessment group, and workshops with experts from academia, industry and city and regional planning administrations. A number of challenges were faced while attempting to address the inherent uncertainty and data restrictions. The outcome of this work is a methodological framework to assess the environmental and social impacts of future scenarios. The framework is using life cycle thinking however differs from the traditional LCA trying to deal with a broad and complex object and scope of assessment and the inherent uncertainty and data restrictions for future scenarios. Unlike a traditional LCA this framework does not really using precise data and modeling all related processes. Instead, more qualitative analysis is done. The learning process of developing the framework and performing the assessment has, as in LCA, been a major benefit and outcome. Key words: Future scenarios, Life cycle thinking, Environmental impacts, Social impacts

### WE343

#### Guideline for conducting a suitable sensitivity analysis in life cycle assessment: considering correlations and interactions within the calculation model

w. wei, Irstea Clermont Ferrand; P. Larrey-Lassalle, IRSTEA Montpellier; T. Faure, LISC IRSTEA; N. Dumoulin, Irstea - Lisc; P.C. Roux, Irstea / UMR ITAP ELSA; J. Mathias, Irstea Lisc  
Sensitivity analysis (SA) studies the robustness of results and their sensitivity to data quality and associated assumptions or models. It highlights the most significant set of model parameters to determine whether data quality needs to be improved, and to enhance interpretation of results. SA has become an important tool for limiting the number of parameters that have to be introduced in the uncertainty analysis for the last two decades. A significant number of sensitivity methods are available. Each method presents its own strengths and weaknesses. Here we propose a methodology for conducting a proper SA which takes into account the effects of two main issues in the LCA calculation process: (i) interactions within the LCA calculation model and (ii) correlations within Life Cycle Inventory (LCI) input parameters. Interactions are produced by the LCA calculation model itself and due to explicit causality relations. Correlations describe the relationship between random variables and are involved in the LCA inputs. Three typical SA techniques are considered here. The first is the **local SA** that focuses on identifying the important factors, which is particularly well adapted for a high number of uncertain parameters. The second is the **independent global SA** analyzes the variability of results due to the variations of the input parameters over the whole domain of uncertainty, together with interaction effect among parameters. However, having independent parameter is the necessary condition for applying independent global SA. To overcome this limit, we then consider a third approach, the **dependent global SA** that makes minor modifications to traditional Sobol indices, which takes into account the correlations within LCI data. This approach has never yet been done in LCA. Finally, we propose a guideline for choosing the appropriate SA method depending on the characteristics of the model and the goals of the study. Our results clearly show that the choice of sensitivity methods should be made according to the magnitude of uncertainty and the degree of correlation.

### WE344

#### Engineering Sustainability: Choice of Unsaturated Polyester Resins for cc-GRP Pipe Systems

V. Vladimirov, HOBAS; M. Pazdro, REICHHOLD AS  
In today's economy efforts are taken towards re-using of available resources and using of resources which are re-generable, thus reducing the impact on the environment. For the polymer industry the development of alternative and renewable raw materials represents an essential task. The study evaluates the different choices of unsaturated polyester resins (UPR) for production of centrifugally-cast glass reinforced pipe (cc-GRP) systems. The environmental impacts of three types of resin were evaluated and compared. The resins are: UPR standard, UPR containing recycled PET material (rPET-UPR) and UPR containing bio-sourced material (BIO-UPR). The analysis focuses on comparing the variations in environmental indicators caused by resin selection for three increasingly complex product layers (Base plate of cc-GRP shaft, cc-GRP Shaft and 1km cc-GRP Pipe-system). The study equally provides an insight onto R&D and LCA collaboration across the supply-chain. One of the main challenges in LCA today is

using specific data from the suppliers instead of generic data. The paper indicates how LCA tools and established R&D processes can be employed to transfer LCA calculations across the supply-chain. The use of specific BIO-UPR resin selected for evaluation results in higher environmental indicators than for the standard product (i.e. "total renewable energy", "net use of fresh water" or "depletion of abiotic resources"). On the other hand, the bio-based component is just one of many production components. Particularly, high share of styrene and propylene glycol (PG) tend to increase values (i.e. CO<sub>2</sub>-eq emissions calculated for PG or Styrene are twice as high as for the bio-component used in production). Knowing this, it is possible to design new bio-based resins having more favorable sustainability footprints than those in-use today. The use of rPET-UPR results in better environmental indicators for the final product, especially as the quantity of material increases (i.e. for 1km pipe system). BIO-UPR and rPET-UPR are alternatives which are realistic in terms of costs and which ensure the required quality for the manufactured products. rPET-UPR can be used for production of complete pipe systems, with positive environmental indicators. Mechanical proprieties of BIO-UPR restrict its usability and use of this resin presents similarities with the debate regarding use of bio-diesel.

### WE345

#### New tool, Life Cycle Risk Assessment (LCRA): application to renewable energy pathways

M. LICHOU, IRIAF / Gestion des Risques; P. ROUSSEAU, Université de Poitiers / IRIAF  
The concept of "Life Cycle Thinking" is not taken into account in traditional risk analyses. To integrate this fundamental concept to the risk analysis methodology, we propose a new method called "Life Cycle Risk Assessment" (LCRA). Following the model of the LCA methodology, we made some adjustments to the risk analysis methodology. Each of the four steps of LCA has its counterpart in terms of LCRA. The variations between these two methodologies reside on two key steps of LCA: the inventory and the assessment. The inventory collects data whose nature is different between the two tools. For LCA, collected data are matter and energy flows: these data are qualitative and quantitative ones. For LCRA, the data collected are only qualitative since it is an inventory of dangerous situations. The assessment step consists of three sub-steps: classification, characterization and valuation, and allows a conversion of inventory data into results of impact / risk levels. For LCA, the conversion of inventory data is performed by a calculation using impact category indicators. For LCRA, this conversion is done qualitatively by rating and prioritizing risks. However, the goal of sub-step classification is the same in both tools because it links the inventory data and the impacts/risk to be assessed. Just like the flow identified by a LCA that can contribute to different categories of impacts, dangerous situations can cause different types of accidents. We illustrate the LCRA method by a case study: comparison of the risks associated to the wind and photovoltaic energies. The interest to consider the life cycle in a risk analysis is to identify and quantify the transfers of risks towards the different stages of the life cycle. We show that raw material acquisition or dismantling can be much more dangerous than the use. It is then possible to check the principles of the sustainable development for the criterion "Health & Safety". LCRA can be very useful in the context of social acceptance of technologies considered as dangerous. LCRA is an operational tool and applies to all life cycles. However, LCRA evaluates only the risk of death and it is difficult to have a good accuracy on the results. This method is not designed as a precise tool to assess the risks but is used to consider the entire life cycle in a risk analysis. LCRA is a perfectible tool and raises some questions in terms of completeness of the inventory of dangerous situations.

### WE346

#### Social LCA: a text mining analysis for critical review

G. Arcese, University of Roma Tre / Business Studies; M. Lucchetti, University of Roma Tre / Department of Business Studies; I. Massa, Università La Sapienza; c. valente, Ostfold Research  
Social Life cycle Assessment (SLCA) is an assessment technique to evaluate potential positive and negative social impacts of product/service and production using a life cycle perspective, lacking of standard and code of practice. The guidelines from UNEP/SETAC (2009) and the recent handbook for products (Fontes et al. 2014) are not sufficient for responding to a need of methodology deepening and consolidation. Hence, the present study intends to classify the wide variety of contributions on SLCA in order to trace the evolution of the theme and to define the main lines of research. The use of cluster analysis enables to map the main orientations present today in the literature. The methodology chosen to conduct a comparative analysis of the literature is the automatic text analysis. The corpus of texts inspected consists in 51 articles all strictly concerning the SLCA published between 2006 and October 2014. The scientific works were collected on the main bibliographic database selecting all available articles containing 'Social LCA' in the title, the keywords, in the text and in the conclusions. Through TaLTaC2 Software several articles were investigated by statistical analyses comparing different lexicon-textual profiles occurring in the corpus (Bolasco 2013). For the variable 'year of publication' both positive and negative specificity were calculated showing the research topic that characterize each period. The analysis of lexical correspondences shows clusters of authors identified according to the similarity of specific words and expressions. Text exploration provides an overview of different solutions currently used in social LCA studies. Therefore a

plurality of methodologies on impact and risk assessment are emerged in the analyzed articles. Preliminary results show the absence of agreement on key aspects such as functional unit, system boundary, bottom-up and top-down approach etc. threatening the consolidation of this methodology. Weak and strong points of this technique will be presented in a critical discussion. The conclusion from our study is that it is challenging to classify the approaches in social life cycle assessment communities, but at the same time, the critical review will help to identify the key factors on which research should really focus. **Keywords:** Social LCA, Automatic Text Analysis, Clustering, Life Cycle Approach

#### WE347

##### **Environmental assessment of a varied productive reality: the case of Grana Padano Protection Consortium**

S. Corrado, Università Cattolica / Institute of Agricultural and Environmental Chemistry; A. Stroppa, Grana Padano Protection Consortium; G. Piva, M. Trevisan, Università Cattolica del Sacro Cuore / Institute of Agricultural and Environmental Chemistry

The sustainability of the agro-food system, main theme of EXPO2015, is an important challenge for producers all around the world. The Grana Padano Protection Consortium, important protagonist of the Italian gastronomic tradition, wants to be part of it. Therefore, the Consortium is approaching the theme of environmental sustainability of Grana Padano starting from the evaluation of its environmental performance. The Grana Padano Consortium covers a large territory in the Po Valley and groups a big number of productive realities: in 2013 it comprised 4634 farmers, 132 dairies, 156 maturers and 177 packagers. The geographical localisation, the dimension of the plants and other parameters influence management choices and result in a quite varied reality. In this context, the present study, carried out by Università Cattolica del Sacro Cuore and following the criteria of Life Cycle Assessment (LCA) reported in ISO standards 14040:2006 and 14044:2006, aims at defining a benchmark for the environmental performance of Grana Padano and at comparing different practices in order to identify which are the more suitable. The evaluation of the benchmark is based on the definition of a representative cheese supply chain actors sample, composed by milk and cheese producers, maturers and packagers. The criteria for the sample definition are the plants geographical location, mainly significant for milk production influencing the cow ration, and the plants dimension. Comparison among different practices is done on the basis of the criteria chosen for the sampling. The assessment follows the approach *from cradle to gate*, from the milk production to the packaging of cheese. The functional unit of the study is one kilogram of Grana Padano - 9 months ageing. The LCA is based on primary data collected directly from the supply chain actors. The first results on the impact on climate change underline that milk production is the process that mostly affect the environmental performance of Grana Padano, accounting from 89% to 96% of total GHG. Particularly, methane emitted from ruminal and enteric fermentation and manure management is responsible for about 40% of the GHG emissions. The presence of a biogas plant, fed with manure, both at the dairy or at the farm, reduces largely the emissions of methane and nitrous oxide, with benefits for the impact on climate change. Further results, including other impact categories, will be presented at the conference.

#### WE348

##### **How the public transport can be green? - Cooperating analysis between Miskolc and Novi Sad**

K. Szita Toth, University of Miskolc / Institute of World and Regional Economics; R. Sándor Bodnárné, Bay Zoltán Nonprofit Ltd. for Applied Research / Department of Environment Management and Logistics; L. Budak, University of Novi Sad, Faculty of Technical Sciences / Production engineering

One of the main research topics of Horizon 2020 aims on developing a resource efficient transport, i.e. how to decrease the environmental impact of public transport in the cities. Our paper's goal is to analyse the recent impacts and situation related to public transport in the bigger towns, with population of 100000 inhabitants and over. The applied methods for the analysis is LCA. In the first stage we determined the function unit, which was the 10 km distance travelled. The system boarder was extended from vehicle production to end of use. The analysis incorporated the tram, bus, electrical bus and local train traffic. Obtained results presents the environmental impacts' dependence on type of vehicle, fuel, age tree and rate of capacity utilisation. The goals of this research are to develop and investigate different scenarios from environmental impacts' point of view, to give proposals to the decision makers of public transport organisations for developing their public systems in more environmental way, toward the sustainable traffic system. The comparative analysis focuses firstly on the public transport systems of Miskolc and Novi Sad, what we later would like to extend on other member's towns of CASE LCA network, and prepare a project proposal during the Horizon2020. Since our goals are focused on analysing the greening process of public transport, beside environmental impacts, the social and economic impacts will be investigated as well.

#### WE349

##### **Life Cycle Assessment for the Sustainability of Contaminated Site Remediation**

C.C. Zhang, Environmental Sciences; V. Yassinskiy, University of Houston Clear Lake / Department of Environmental Sciences

A limited number of case studies have been conducted to date on the use of Life Cycle Assessment (LCA) for the evaluation of sustainability of contaminated soil and groundwater remediation. These studies have generally suggested the usability of LCA but also pointed to the methodological flaws and other issues related to the complex remediation systems which hamper the use of LCA by practitioners and for decision-makers to ultimately incorporate sustainable strategies into soil and groundwater remediation. We have employed openLCA software and ELCD database to examine past, on-going, and alternative remediation scenarios on the Geneva Industries Superfund site, Houston, Texas, including remote landfill, protective cap, slurry wall, continuous pump-and-treat (P&T), pulsed P&T and monitored natural attenuation (MNA). LCA serves well as a retrospective as well as a prospective impact analysis tool for the comparison of sustainability among remediation scenarios and suggestions for potential improvement toward sustainability. For example, LCA results confirmed that remote landfill was more sustainable than local incineration but the slurry wall already in place was the least sustainable subsystem with its construction materials contributed over 98% in most impact categories. LCA results also imply that future remediation should adopt pulsed P&T scheme in lieu of continuous P&T, whereas MNA can replace P&T if a long-term 30-year remediation is permitted at the site. In line with several reported studies, we concluded that current LCA methodology tends to favor less invasive remedial options and overestimate the material and energy related secondary environmental impacts rather than the direct benefits of reduced primary environmental impact at the local level which is the true driver for the implementation of sustainable remediation. The burden of streamlined data suitable for remediation use and the lack of assessment for social and economic pillars essential to sustainable remediation are identified as the major impediments for the widespread acceptance of LCA in environmental remediation. General solutions with these shortcomings will be illustrated with our case study data and future research and development opportunities in sustainable remediation will be highlighted in this presentation.

#### WE350

##### **Comparative LCA of decentralized wastewater treatment alternatives for non-potable urban reuse**

T. Opher, E. Friedler, Technion - Israel Institute of Technology

Traditional approaches to water management have focused on modifying water storage and flow patterns. However, in a growing number of cases the available water is not sufficient to meet basic water needs. In urban areas often attainable water sources have been over-allocated and new water sources which can be cost-effectively developed are no longer available. Water conservation, which was viewed in the past as a temporary measure for times of drought or emergency water shortages, is nowadays regarded as a viable long-term option with benefits for water utilities, environment and community. With many communities approaching the limits of their readily available water supplies, water reclamation and reuse has become an attractive option for conserving and extending available water sources. Municipal wastewater (WW) represents a reliable and significant source for reclaimed water, as it is consistently available, even during periods of drought. Centralized wastewater reclamation and reuse has become commonplace in urban areas worldwide, but the advantages of the centralized approach over decentralized ones are questionable. In this study we use Life Cycle Assessment to compare between the environmental impacts of four alternatives for a hypothetical city's water-wastewater service system. One is the most common, centralized approach for WW treatment, in which WW is treated at a large wastewater treatment plant (WWTP) and is then discharged to the river. The three alternatives represent different scales of distribution of the WW treatment phase, along with urban domestic water reuse for non-potable uses (toilet flushing and landscaping). The first alternative includes centralized treatment at a WWTP, with part of the reclaimed WW supplied back to the urban consumers. The second and third alternatives implement de-centralized WW treatment with local reuse, one at cluster level (several multi-family buildings) and one at building level (40 households). Life cycle impact assessment results show a consistent disadvantage of the prevailing centralized approach under local conditions, consisting of seawater desalination as the marginal source of water supply. Relative scores of the other three alternatives vary across different impact categories. Contribution of the different sub-systems to the total score is discussed and sensitivity analysis in regards to major model parameters, such as water source and electricity mix, is presented.

#### WE351

##### **Environmental performance assessment of football fields with synthetic grass made by using natural filler or rubber filler from end of life tires recycling**

S. Sbaffoni, L. Cutaia, ENEA

Rubber coming from recycling of end of life tires (ELT) can be used both as material for manufacturing new products and for energy recovery. According with the European waste hierarchy, recovery as material for new products should be preferred than the use for energy recovery. Among the possible uses as material, recycled rubber can be used as filler in football fields with synthetic grass. In Italy there is a huge production of ELT, about 300.000 tons/yr, and about 70% is used for energy recovery. Nevertheless the use of ELT as material is increasing and about 10% of recovered ELT are used for sport fields and applications in the sport sector. The use of recycled rubber from ELT for football fields, despite its growth, is

subjected to a parallel growing in concerns for possible impacts coming from rubber or its components dispersion into the environment and for the health of the users. In order to try to understand main impacts coming from the above cited issues, the present work shows main results of a comparative analysis of environmental performances of synthetic grass football fields with filler in rubber from ELT or with organic filler. The evaluation has been made using LCA methodology according with ISO 14040 series. the functional unit defined for the study corresponds at one football field in synthetic grass for a total surface of 7,668 m<sup>2</sup> and systems analyzed are: RF (synthetic grass football field with rubber filler); deposit of ELT at the generation point, comminution phase with the production of granulate rubber, granulate rubber on site, oil extraction, pretreatments, cracking for the production of light hydrocarbons, polymerisation, production of plastic granulate, production of synthetic grass (including extrusion, texture, rolling and packaging) and its on-site installation; transports from different phases are included. End of life has been considered, including the removal, transport and treatment of synthetic grass layer and filler for their treatment (landfilling and/or recycling). OF (synthetic grass football field with organic filler): as the system above but with filler organic material including production (if primary Raw material) and deposit of organic materials, and end of life treatment. Different performances of the two types of football fields have been taken into consideration concerning in particular the different needs for maintenance and the overall service life of the products (filler plus synthetic grass).

### WE352

#### **Life cycle assessment of vegetative, reflective and traditional roofs: A case study for the Lebanese context**

M. El Bachawati, University of Balamand / Chemical engineering department; R. Manneh, Chemical Engineering; T. Dandres, CIRAIG; C. Nassab, The United Nations Development Program; H. El Zakhem, University of Balamand; R. Belarbi, University of La Rochelle / Laboratory of Engineering Science for Environment LaSIE

**Abstract** A vegetative roof is a "roofing system that promotes the growth of plants on a rooftop". Vegetative roofs offer many advantages, such as an embellishment of the roofing system, an enhancement of water management, and a reduction in energy consumption and heat island effects. Lebanon, a country situated in the Middle East, imports 98% of its energy (non renewables) and experiences flooding during heavy rains. The objective of this research is to determine if the installation of vegetative roofs is truly superior to traditional roofs for the Lebanese country. A life cycle assessment is performed, comparing an existing extensive green roof installed at the Lebanese Central Bank to the following types of roofs: intensive green, reflective and traditional gravel-asphalted. The functional unit used for the comparison is as follows: "The implementation of a roofing system for a surface of 834 sqm and for 45 years". A life cycle inventory was established and modelled using the SimaPro software. Results indicated that, for the existing extensive green roof, the waterproof membrane and the substrate layer were the highest contributors to the potential environmental impacts. When comparing the four types of roofs, results showed that, for all impact categories, the extensive green roof had the less environmental impacts. Sensitivity and uncertainty analyses were also performed to check the robustness of the results. Future research is to be performed on the effect of different substrate composition. Research will also be done on the effect of vegetative roofs on water retention and reduction in energy consumption for the Lebanese country. **Keywords:** Life cycle assessment, green roofs.

### WE353

#### **Challenges in applying LCA at the research stage : case study on biotreatment of pollutants in drinking water resources**

L. Muñoz, 2.-0 LCA consultants; E. de Vries, Bioclear; J. Wittebol, Research projects aiming to develop new technologies, products, and services increasingly use life cycle assessment (LCA) as a means of providing information about the potential for sustainability of the technology under development. While using LCA at this early stage clearly provides benefits in terms of steering decisions towards sustainable choices, this collides with the practicalities of LCA: properly scoping the study, collecting the (sometimes unexisting) data and dealing with the uncertainty of the results from assessing a technology that does not exist yet in the market. We give an overview of the main challenges that the LCA practitioner encounters in this kind of prospective assessments and how they can be overcome, with the example of an LCA of biotreatment of water resources, carried out for the EU-funded project BIOTREAT ([www.biotreat.org](http://www.biotreat.org)). BIOTREAT aims at developing new technologies for bioremediation of drinking water resources contaminated with micropollutants such as pesticides and pharmaceuticals. The basis of the proposed technologies is the introduction of specific degrading microorganisms or microbial consortia into existing sand filters at waterworks. We focus on the following aspects : defining the scope (number of scenarios, target pollutants, geographic delimitation, system boundaries), data collection, type of modelling (attributational/consequential), uncertainty (limitations of using lab-scale data and expert judgement) and the integration of LCA results with a parallel economic assessment. In the case study, biotreatment of polluted water in a waterworks is compared to two alternatives, namely granular activated carbon (GAC) adsorption, and re-location of abstraction wells. Besides the LCA, an economic assessment including financial costs is performed, and the two assessments were integrated using monetization of environmental impacts

according to the Stepwise LCIA method from 2.-0 LCA consultants. We show that LCA, applied at the research stage, can provide useful information to technology developers, opening their eyes to a completely different perspective that goes beyond their work in the lab. It is our conclusion that the role of LCA in this context is rarely to provide strong claims, but rather to identify hotspots, and to provide a first quantitative impression of relative performance, where what matters are orders of magnitude and not decimal points.

### WE354

#### **Reflections on User Assertions about LCA Tools**

S. Bajaj, A. Datta, Federation of Indian Chambers of Commerce Industry / Quality Forum; s. gupta, Quality Forum

With economic development imperatives overshadowing environmental concerns and want of scientific knowledge and access to eco-efficient technologies limiting their choices, developing countries like India are in dire need of simple tools that can help evolve and evaluate locally relevant options to manage environmental impacts. They must chart their developmental trajectory in a way that does not import unsustainable consumption and production patterns or make more environmental disasters. Considering the total cost in terms of economic benefits and environmental fixes, many technologies that seem too expensive at the moment may after all be worth their initial cost. Life Cycle thinking with a combination of LCA and LCC tools seems to offer an intuitively appealing method for evolving and evaluating choices both at the national and business policy levels. Choices could include eco-innovations, life styles changes, changes in consumption patterns and volumes, changes in policies regarding production technologies and markets, changes through institutional adaptations, etc. With this background, the questions we address in this paper are: How can Life Cycle Thinking practices and tools help in the Indian context? What governmental and business needs can they meet? How should they be positioned and extended to deliver more value? The paper discusses findings from structured interactions over the past two years with business, government, and community on their assertions about usefulness of LCA tools. The assertions show that prospective users are looking for LCA studies that can help evolve more options for sustainable technologies suited to the local context. They also perceive value addition from LCA through improved understanding of upstream and downstream activities to better manage costs, risks, impacts, etc. In conclusion, we build upon their assertions to present directions for future development of LCA tools that can facilitate evolution and evaluation of options to fulfil some typical goals relevant for developing countries, e.g. global competitiveness, access to affordable energy, cleaner environment.

### WE355

#### **Approach for sustainability assessment guided by life cycle thinking: application to virgin olive oil production**

G. Busset, INP-ENSIACET; J. Belaud, Université de Toulouse INP-ENSIACET CNRS UMR 5503; M. Montrejeaud-Vignoles, Université de Toulouse / INP-ENSIACET LCA Laboratoire de Chimie Agro industrielle INRA UMR CAI; C. Sablayrolles, INP-ENSIACET

**Context & Objectives** Nowadays, any strategic decision must be in accordance with the sustainability principles. Therefore, companies need to evaluate the consequences of their activities and products onto environment, economy and society. Life cycle assessment (LCA) from Life cycle thinking (LCT) is one of the major environmental impact evaluation methods for product, process or service and the trends is to integrate economic and social aspects to become a life cycle sustainability assessment (LCSA). However, LCSA is still in its infancy and needs methodological proposals to be applicable. In this context, the present study proposes a sustainability assessment of the French olive oil agro-industrial sector. **Methodology** In doing so, a systemic approach for decision making and based on the coupling between LCSA, enterprise modeling, chemical process modeling and multicriteria analysis is proposed. The approach relies on a formalization of system modelling for LCSA. It is an integrated process-product-enterprise (P<sup>2</sup>E) approach with a multicriteria analysis. It helps to unleash the following shackles: how to integrate social, environmental and economic aspects for sustainability assessment **Results** The results showed that the approach is effectively applicable and relevant for sustainability assessment. The application to olive oil production has been undertaken in the framework of the OilCA European project [1]. A large amount of data was collected and has permitted to build olive oil processes, product and enterprise realistic models. The results showed that the P<sup>2</sup>E approach is effectively relevant for sustainability assessment. **Acknowledgement** The authors would like to thank the Interreg Program SUDOE for the financial support of the OilCA project. **Reference** [1] OilCA, 2011. Mejora de la competitividad y reducción de la huella de carbono del sector del aceite de oliva mediante la optimización de la gestión de residuos e la implantación de una eco-etiqueta. ### **Fate, Effects and Risk Assessment of Metals: Regulatory Perspective (P)**

### WE356

#### **A simple method to reduce the risk of cadmium exposure from consumption of Iceland scallops (*Chlamys islandica*) fished in Greenland**

L. Bach, Aarhus University (AU), Arctic Research Centre / Department of

Bioscience; C. Sonne, Aarhus University / Department of Arctic Environment; F.F. Riget, Aarhus University; R. Dietz, Aarhus University / Department of Arctic Environment; G. Asmund, Aarhus University / Department of Bioscience Arctic Research Centre

This study investigated the levels and organ distribution of the toxic heavy metal cadmium in scallops from unpolluted Greenlandic waters. The scallops had an average cadmium concentration of  $2.93 \pm 0.94 \mu\text{g/g}$  wet weight in the total soft tissues and no concentration dependent effect was found for gender or size (both  $p > 0.05$ ). The kidney was the primary organ for cadmium accumulation with a mean of  $226.2 \pm 111.7 \mu\text{g/g}$  wet weight, and despite the small weight of the kidney, it appeared as the principal contributor of cadmium with 92 % of the total cadmium body burden. The cadmium concentrations in the total soft tissues far exceeded the EU-limit of  $1 \mu\text{g/g}$  wet weight for cadmium in bivalves. Based on this, selective evisceration of the cadmium-rich kidney and digestive gland during processing can be regarded as a reliable measure to be taken in order to reduce the cadmium content of scallops used for human consumption.

#### WE357

##### **Conversion factors for heavy metals and PFAS for fish muscle, liver and whole body**

S. Faxneld, Swedish Museum of Natural History / Environmental research and monitoring; S. Danielsson, Naturhistoriska Riksmuseet / Department of Contaminant Research; E. Nyberg, A. Bignert, Swedish Museum of Natural History

Environmental Quality Standards (EQSs) (Specific Quality Standards (QS) when EQSs are not available) for priority substances and other pollutants, have been suggested by EU to protect aquatic ecosystems and human beings from adverse impacts of chemical contaminants. Mercury (Hg) is often measured in muscle to ascertain compliance with tolerance limits for human consumption, but the EQSbiota is set to protect predators of fish and evaluates whole body prey fish concentrations. Lead (Pb) and cadmium (Cd) are often measured in liver, but also here QSbiota is set for whole body. PFOS is measured in liver, but the EQSbiota is set to protect human health and evaluates edible parts, muscle or muscle+skin. Thus, if we can assume a relationship between concentrations in various tissues in the same specimen it is imperative to find these relations to enable conversions between various tissues and whole fish, to make the EQS meaningful regardless in what tissue the concentrations are measured. Hence, the aim with this project were to calculate conversion factors between liver and muscle (for PFOS), muscle and whole fish (for Hg) and liver and whole fish (for Cd and Pb) and to establish alternative EQSs or QSs in the various tissues, that can offer at least the same level of protection as the EQSbiota or QSbiota set for each compound. For PFOS, herring and perch were taken at different locations in the Baltic Sea and perch was also taken from several lakes in Sweden. For metal analyses, perch from different lakes in Sweden was used. Samples from liver, muscle and whole fish were taken and concentrations were measured. Thereafter linear regression analyses were performed between the different matrices and the regression line equations were used for each compound in order to recalculate the existing EQSs or QSs. For Hg, the EQSbiota in whole fish is set at  $20 \mu\text{g/kg}$  wet weight (ww), after recalculation the new derived EQS in muscle is  $21 \mu\text{g/kg}$  ww. For Cd, the suggested QSbiota for whole fish is  $0.16 \mu\text{g/g}$  ww and the new derived QS in liver is  $6.6 \mu\text{g/g}$  ww. For Pb, the suggested QSbiota in whole fish is  $1 \mu\text{g/g}$  ww and the new derived QS in liver is  $0.30 \mu\text{g/g}$  ww. For PFOS the EQSbiota is  $9.1 \text{ ng/g}$  ww in muscle and the new derived EQSbiota in liver is  $144 \text{ ng/g}$  ww. When comparing concentrations at the different locations, all lakes had Hg levels above the target level, while for Pb and Cd all lakes were below the target level. For PFOS, one site exceeded the target level.

#### WE358

##### **Tracking temporal trend breaks (abrupt changes) of anthropogenic change in Mussel Watch metal databases**

C. Guitart, Spanish Institute of Oceanography; C. López-Galindo, S. Gregores, Instituto Español de Oceanografía; A. Hernández-del-Valle, Instituto Politécnico Nacional; J.M. Marín, Universidad Carlos III de Madrid; J.M. Benedicto, J.A. Campillo, Instituto Español de Oceanografía; M. Albentosa, Instituto Español de Oceanografía / Centro Oceanográfico de Murcia

The potential for structural changes in time trend concentrations of mercury (Hg), lead (Pb), cadmium (Cd), zinc (Zn), and copper (Cu) in the Mediterranean mussel, *Mytilus galloprovincialis*, was examined in Mussel Watch (MW) databases of metal pollution at eighteen coastal stations over a decadal period (1992 to 2007) along the Spanish Mediterranean coasts. Simultaneously, by using two statistical methods representing both the classical hypothesis-testing and the Bayesian approaches (imported from econometrics), we found single and multiple trend breaks for Hg (28% of the stations), Cd (17%), and Pb (11%) within trends, in connection with anthropogenic and subtle natural environmental changes. Also called change point problems, if not accounted for, these could bias time trend investigations and interpretations. We calculated trend rate differences of 39% and switches up to 1 order of magnitude from classical linear trend assessments. We discuss sampling, analytical, and environmental (both natural and anthropogenic) sources of data set variabilities, showing that in practice, the overall 16-year analytical performance could be as elevated as the yearly sampling reproducibility. We demonstrate that environmental time trend interpretations benefit from

undertaking prior structural change analysis. After decades of Mussel Watch marine chemical pollution assessments these have proven extremely useful, although the occurrence of trend breaks directly affects the long-term marine environmental monitoring strategies. Our results suggest a broader concept to design monitoring programs in agreement with rapid global anthropogenic and environmental changes.

#### WE359

##### **Mussels in the Gulf of Naples (Italy): from industrial production to sustainable fishery**

R. Scudiero, Department of Biology; M.G. Esposito, University Federico II of Naples; F. Trinchella, University Federico II of Naples / Department of Biology; P. Cretì, University of Salento

In the recent years, the decline of wild aquatic organisms has led to the expansion of aquaculture in Italy. Among the molluscs, the edible mussel *Mytilus galloprovincialis* is the most sold in the Southern Italy, and the animals come almost exclusively from aquaculture. The Gulf of Naples is a 15 km coastal area located in the Campania region, subject to pollution from highly populated urban centers, port activities, and large industrial complexes, including oil refineries. Nevertheless, nowadays many mussel farms have been arising in this area following the closure of many important industries (the steel plant ILVA, for example). We monitored the quality of the mussels *M. galloprovincialis* farmed in this area converted to more environmentally friendly practices, in terms of heavy metal contamination. The concentration of toxic heavy metals (Pb, Cd) was determined on edible tissues of *M. galloprovincialis* specimens collected at different aquaculture farms. On the same animals was also determined the amount of metallothionein, the most important biomarker of metal pollution. The collected data were compared with those obtained from animals belonging to natural banks located in the same area, from animals belonging to farms located in pristine areas and from animals relaying in metal free seawater, in order to establish public health risks associated with consuming mussels harvested in the Gulf of Naples. Results show that the Pb and Cd contents in mussels from the Gulf of Naples do not represent a risk to human health, even in the period of their maximum accumulation, that do not depend on the harvesting or farming area, but rather on the seasonality. Indeed, in all instances the levels of the two metals were lower than the limits established by the European Food Safety Authority (EFSA 2005), that are  $1 \mu\text{g/g}$  wet tissue for Cd and  $1.5 \mu\text{g/g}$  for Pb. Data further demonstrate that the metallothionein functions go beyond the metal detoxification, thus opening new scenarios for the role of this protein in invertebrates. Finally, the relaying of mussels before marketing could improve the animals stress conditions, but would seem to have a slight effect on metal excretion, at least for the relaying period considered in this work. Thus, we may conclude that the conversion of industrial sites in areas devoted to aquaculture represents a real opportunity to increase the number of companies and employees in fisheries production.

#### WE360

##### **Assessment of the sensitivity of European freshwater environments to chronic copper toxicity**

A. Peters, Wca Environment Ltd.; G. Merrington, Environment Agency; I.A. Wilson, WCA Environment Ltd; K. Delbeke, European Copper Institute; P. Van Sprang, ARCHE

Given the move within Europe towards the regulation of the levels of some metals in surface waters on the basis of bioavailability it is important to understand the variation in metal sensitivity that may be exhibited across the range of water chemistries. Bioavailability based Environmental Quality Standards (EQS) have been proposed for several metals, including copper, in the UK under as Specific Pollutants, and nickel as a priority substance across the whole of Europe under the Water Framework Directive. Chronic copper toxicity is highly dependent upon the water chemistry conditions, particularly the dissolved organic carbon concentration. At present there is insufficient information available about how European surface waters vary in terms of their copper sensitivity to understand where the areas of high and low sensitivity exist. An assessment of available databases of surface water chemistry throughout Europe has been performed to collate freely available data which can be used to estimate the bioavailability of copper under the local water chemistry conditions. Local site specific estimates of the EQS for copper under the local conditions have been made for each site. Data for a total of 2079 sites from six European countries (Austria, Denmark, France, Poland, Sweden, and the United Kingdom). These countries exhibit a range of water chemistries, from relatively acidic conditions in Sweden to relatively high pH conditions in Poland and Austria. Very soft water conditions are found in Sweden and Scotland, compared to hard water conditions in France and England. Dissolved organic carbon concentrations are greatest in Poland and Sweden, and are lowest in Austria and France. The most sensitive water chemistry conditions for copper are expected to occur in Austria and France, due to low levels of dissolved organic matter in the local surface waters.

#### WE361

##### **Development and application of predictive bioavailability models for the derivation of safe thresholds for assessing chronic nickel toxicity in freshwater sediments**

M. van Gheluwe, ARCHE; M.A. Nguyen, Lab of environment toxicology and

aquatic ecology; E.R. Garman, NiPERA / Ecotoxicologist; C.E. Schlegel, NiPERA; K.A. De Schamphelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit

The protection of the sediment ecosystem is embedded in regulatory frameworks such as the European Union regulatory initiative for the Registration, Evaluation, Authorization and Restriction of Chemicals (REACH) and the EU Water framework Directive (WFD). In general the limited availability of appropriate sediment toxicity data and the lack of understanding of how certain sediment characteristics may modify contaminant bioavailability hamper the process of determining risk to the sediment compartment. This study presents the final results of a comprehensive research program aimed to develop predictive, mechanistically based bioavailability models that can be applied across broad ranges of sediment chemistry to be applied to a suite of sediment organisms exposed to nickel. Bioavailability models were developed for a total of six species differing in life strategy and feeding habits: the amphipods *Hyalella azteca* and *Gammarus pseudolimnaeus*, the oligochaete *Tubifex tubifex*, the insect *Chironomus riparius*, the mollusc *Sphaerium corneum* and the mayflies *Hexagenia* sp. and *Ephoron virgo*. All models demonstrated a positive correlation with several sediment characteristics but the strongest relations were shown for Acid Volatile Sulfides (AVS). The organisms responses show a dichotomous pattern where the slopes of the bioavailability models developed for the mayflies (*Hexagenia* and *E. virgo*) were less steep than for the other species, which resulted in less responsive models towards increasing AVS concentrations. A possible explanation of the observed differences could be the specific behaviour of mayflies such as micro-habitat formation. The models were subsequently used to normalize the existing sediment Species Sensitivity Distributions towards prevailing AVS concentrations in the real environment. Using the 10<sup>th</sup> to 90<sup>th</sup> percentiles of the distribution of AVS in European freshwater surficial sediments resulted in HC5(50%) values ranging from 109 to 305 mg Ni/kg sediment.

### WE362

#### **Derivation of ecological quality standards for metals in soil: towards a common database**

K. Oorts, ARCHE; I. Schoeters, Rio Tinto

Since 2000, a wealth of information has been collected on bioavailability and toxicity of metals to terrestrial organisms (plants, invertebrates and micro-organisms). This work was mainly triggered by the European legislation on chemical management (REACH and the former Existing Substances Regulation) and the data were therefore primarily used for risk assessment purposes. Chronic EC<sub>10</sub> or NOEC data were used as a basis for the assessment. For several metals (e.g. Cu, Co, Ni, Zn, Pb, Mo, Cd), the Predicted No Effect Concentration (PNEC) under REACH is typically based on the 5% Hazardous Concentration (HC<sub>5</sub>) as derived from the species sensitivity distribution (SSD) based on these reliable EC<sub>10</sub> or NOEC values after correction for differences in bioavailability among soils or between laboratory and field conditions. This PNEC is derived for risk assessment purposes and not directly useful for setting other soil threshold concentrations, e.g. for soil remediation. In the latter case, a small degree of effects to some groups of terrestrial organisms is generally accepted before it is decided that the contamination poses an unacceptable risk to the environment or human health and hence must be removed and the level of effects accepted often depends on factors like e.g. land-use (agricultural, nature, industrial, ...). Moreover, in some jurisdiction, other effects parameters (e.g. EC<sub>20</sub>) are preferred over EC<sub>10</sub> or NOEC values. In order to facilitate the setting of ecological quality standards for metals in soil for different protection purposes (risk assessment or remediation) and in different jurisdictions, while still making maximal use of the wealth of data and models already available, e.g. under the framework of the European risk assessments, it is proposed to use the same data and tools towards a more flexible derivation of soil toxicity thresholds. This can be done by allowing selection of the different effects level (e.g. EC<sub>10</sub>, EC<sub>20</sub>, EC<sub>30</sub> or EC<sub>50</sub>) as a basis for the assessment, selection of the hazardous concentration within the SSD (HC<sub>x</sub>), selection of group of organisms to be protected, selection of bioavailability models to be included, etc. The advantages of this approach are harmonization of toxicity datasets and bioavailability models used and consequently the enhanced transparency in the derivation of ecological quality standards for metals in soil for different goals and different scenarios.

### WE363

#### **Ecotoxicity of two oxidation states (+IV and +V) of vanadium (V): Implication for risk assessment of steelmaking slag as material for the agricultural soil improvement**

O. Penttinen, University of Helsinki / Faculty of Biological and Environmental Sciences; I. Reijonen, University of Helsinki / Department of Food and Environmental Sciences; M. Laiho, University of Helsinki / Department of Environmental Sciences Lahti; M. Lares, University of Helsinki / Department of Environment Sciences Lahti; H. Hartikainen, University of Helsinki / Department of Food and Environmental Sciences

Vanadium is one of the heavy metals with environmental interest. Large amount of V enter the environment both from natural and anthropogenic sources including crude oil, combustion of fossil fuels and steel industry. In addition, steelmaking

slag with up to 3 % vanadium content have many uses e.g. in agriculture. Part of the slag vanadium is in bioavailable form and thus posing potential threat to soil fauna. From a risk assessment perspective more ecotoxicological information is required for vanadium both in soils and solutions. Chemistry of the vanadium is complex and involves a wide range of oxygenated species but in environmental solutions only two oxidation states are stable, +IV and +V, from which +V is considered more toxic. In this context, questions of metal-specific factors (V oxidation state), exposure related issues (soil and water pH, DOC, soil OM), biological factors (sensitivity of test species, aquatic vs. terrestrial), and slag quality (V content, bioavailable vs. non-bioavailable V) need to be addressed being the main focus of this study. Ecotoxicity of two V oxidation states, vanadyl sulphate VOSO<sub>4</sub> (+IV) and metavanadate NaVO<sub>3</sub> (+V) were investigated both in water, and with two test soils: surface soil (OM 3.5%) and coarse mineral subsoil (OM 0.5 %). The pH of the test soils and waters were adjusted to three levels common in Finnish environment. The standard toxicity tests were performed by using earthworm *Aporrectodea caliginosa*, and for comparison cladocerans (*Daphnia magna*), bacteria (*Vibrio fischeri*), and duckweed (*Lemna minor*). The median lethal concentrations for earthworm ranged from 87.0 to 232.2, and from 76.9 to 305.5 mg V/kg soil DW for NaVO<sub>3</sub> and VOSO<sub>4</sub>, respectively. The subsoil with high pH promoted the highest toxicity. Of the four slags studied, steel slag from Raahe steel factory was the most toxic for the earthworms. In aquatic toxicity testing *D. magna* was the most sensitive species with median lethal concentrations range from 0.08 -1.77 mg V/L, and from 0.05-1.24 mg V/L for NaVO<sub>3</sub> and VOSO<sub>4</sub>, respectively. EC50 values for *Lemna minor* were in the range from 0.04 to 10.9 mg V/L reflecting again the importance of bioavailability issues. Only minor toxicity was observed in the experiments performed with *V. fischeri*. In terms of V risk assessment our results increased ecotoxicological information regarding species sensitivity, importance of exposure conditions, V chemistry and complex interactions of factors given above.

### WE364

#### **Sustainable recycling industries in developing countries - State of the art of recycling metal standards and certification schemes**

S. Valdivia, UNEP / Secretariat ILCI; S. Valdivia, Pontificia Universidad Catolica del Peru

The world's consumer class is growing at exponential rates especially in the emerging and rapidly growing economies and so is the global resources consumption and waste generation rates. Metals are essential materials used in all industrial sectors and their availability is under risk in the mid- and long-term due to increasing prices and scarcity index. Recycling of metals has become a crucial activity worldwide and is well spread also in developing countries to ensure the supply of these valuable resources. However, metal recycling practices especially in developing countries still lack of sufficient recognition from key local stakeholders (e.g. local and national Government and consumers), resources and supporting infra-structure which is leading to acute social impacts on concerned actors around the recycling activity and low metal recovery efficiency. The Sustainable Recycling Industries Initiative (SRI: [www.sustainable-recycling.org](http://www.sustainable-recycling.org)) is an international effort which has the aim to build capacity for sustainable recycling in developing countries. It is mainly funded by the Swiss Government and implemented by the World Resources Forum jointly with the Swiss Institute for Materials Science & Technology (Empa) through three components: Global Roundtable for Sustainable Recycling (GRSR): a stakeholder consultation process will be setup to support the development of guidance principles for sustainable recycling standards (GP4SRS) of critical and valuable metals. Capacity Building: Local capacities of SMEs for sustainable recycling will be strengthened in Colombia, Egypt, Ghana, India, Peru and South Africa. Life Cycle Inventories: Data will be developed to assess environmental and social life cycle performance for industrial activities through the improvement of local and regional expertise in Brazil, India and South Africa. The focus of this paper will be on the GRSR to be integrated by international partners and regional or sectoral initiatives such as the Waste Electrical and Electronic Equipment Forum, The Aluminium Standard Initiative, The World Gold Council, The OECD, among others. As the basis for the development of GP4SRS, it was identified the need to have a clear picture on key stakeholders as well as the state of the art of metals standards development and certification schemes. The aim of the paper is to provide an update on the GRSR setup and a landscape of current recycling metal standards and certification schemes as part of the SRI project.

### **Reflections on bird and mammal risk assessment: past, present and future (P)**

### WE365

#### **Bird community monitoring in chlorpyrifos-treated wheat fields in UK - breeding success and behavioural aspects**

R. Dittich, Tier3 Solutions GmbH / Wildlife Ecology; B. Giessing, Tier3 Solutions GmbH; M.M. Benito, Wildlife Ecology; P. Machin, Tier3 Solutions GmbH; S. Norman, RidgewayEco; N.N. Poletika, Dow Agro Sciences LLC / Field Exposure and Effects Department; C. Wolf, Tier3 Solutions GmbH

If a plant protection product which could pose a risk to birds is applied, it is important to understand the ecology of the bird community present in the target

crop in the application period in order to conduct a proper risk assessment. Therefore the aim of this study was to monitor the bird populations in wheat fields in UK, and to estimate the possible effects of the use of chlorpyrifos (CP) against orange blossom midge. The methodology for observation of the bird community present in arable land was adapted following the landscape approach. The main challenge is to deal with the year-to-year change (rotation) of the cultivated crop on single fields. Furthermore, winter cereal fields are characterized by a lower abundance of breeding pairs and a lower diversity of species than other agricultural areas, e.g. orchard systems. As counterbalance, birds are more visible within the arable landscape. The study was conducted in 2013 and 2014 in Cambridgeshire, an area representative for wheat cultivation and the use of CP. The subjects of the study were birds making use of treated and untreated cereal fields. In order to find birds actually nesting within the fields, systematic nest searches were conducted regularly, by two combined methods: rope-dragging and watching-back. To obtain information on communities of birds present in arable fields, systematic observations of the number and species were conducted from selected positions using binoculars. Additionally, in 2014 a selection of birds was radio-tagged to check for changes in habitat use following the CP application. In 2013 there were 94 nests from 18 different species discovered in the study fields and their close surroundings. Only Skylark and Yellow Wagtail nests (35) were actually found within the crop itself. In 2014 the nest search focused on these two species, and in total 75 and 31 nests of Skylark and Yellow Wagtail respectively were monitored for fate. The results of the nest monitoring allowed the comparison between proportions of successful and unsuccessful breeding attempts in both treated and untreated fields, and revealed the causes for nest failure. On the other hand, the radio tracking procedure in Skylarks and Yellow Wagtails, performed before and after the application of CP, demonstrated how the birds adapted their foraging behaviour after the application, and allowed to assess the potential consequences of this change on the breeding success.

### WE366

#### **Radio-tracking of birds - versatility to assess effects and spatial aspects of foraging behaviour**

B. Giessing, Tier3 Solutions GmbH; R. Ditttrich, Tier3 Solutions GmbH / Wildlife Ecology; M.M. Benito, Wildlife Ecology; A.A. Fernandes, F. Sotti, Tier3 Solutions GmbH; S. Norman, RidgewayEco; N.N. Poletika, Dow Agro Sciences LLC / Field Exposure and Effects Department; C. Wolf, Tier3 Solutions GmbH

If plant protection products are applied which pose a risk to birds, it is important to quantify the exposure. Theoretically birds might be exposed by direct over-spraying or by oral exposure through foraging on arthropods or plant material after application. Whether these theoretical pathways happen depends on the behaviour of the birds. Therefore it is essential to monitor the behaviour of the birds. The method of choice should (i) demonstrate exposure and (ii) monitor the medium-term survival of the birds after exposure. Moreover, it should (iii) detect potential behavioural change caused by the application which may induce a variance of the theoretically expected exposure to the birds. In order to monitor birds using habitats for foraging where the insecticide chlorpyrifos is used we applied the radio tracking technique. In citrus orchards in Spain, in cider orchards in the UK and in winter cereal fields in the UK bird individuals were equipped with radio tags in order to monitor their behaviour continuously for at least one daylight period before and after the application of chlorpyrifos. Moreover, regular checks served to monitor the medium-term survival of the birds. Bird daily home range was estimated using Kernel Density method. The majority of tagged birds used the orchards for foraging before and after the application and therefore were theoretically exposed. However, some bird species changed their home range towards non-treated habitats in the surrounding and decreased the proportion of diet they obtained from the treated habitat. Hence, birds are obviously able to react to changes in their home range caused by insecticide application by altering their foraging strategies and thereby reducing the risk of exposure to the residues. The regular checks of the birds revealed their well-being. The obtained results demonstrate the versatility of radio-tracking for obtaining the desired information. The method is sensitive (i) to demonstrate potential exposure by proving the utilisation of the treated habitat; moreover, (ii) the survival of the birds could be monitored over a reasonable time period after the insecticide treatment; and (iii) the method reveals strategies on how birds are able to adapt to reduced arthropod biomass (by insecticide application) by adjusting their foraging behaviour. Hence radio tracking is a valid method to monitor the behaviour of birds essential for assessing the potential impact of plant protection products application.

### WE367

#### **Focal Species of Birds in European Crops for Higher Tier Pesticide Risk Assessment**

P.J. Edwards, Central Product Safety Dept; C. Dietzen, Rifcon GmbH; C. Wolf, Tier3 Solutions GmbH; J. Ludwigs, Rifcon GmbH; J. Pascual, BASF SE; R. Luttik, Focal species have been defined by the European Food Safety Authority (EFSA) as real species that represent others in a crop resulting from their potential higher level of exposure to pesticides. As such they are the most appropriate species for refining estimates of exposure further, through for example radio-tracking and dietary studies. Plant Protection Product manufacturers collectively commissioned many studies in Europe, according to the EFSA guidelines, in order to identify focal species in different crops that may be used in risk assessments for spray

applications of pesticides. Using frequency of occurrence in crops and risk based criteria for exposure, all studies have been reviewed to identify if possible at least one focal species per feeding guild, per crop in the new registration zones for southern and central Europe. Some focal species repeatedly appeared across a wide range of arable or tree crops, but not both, demonstrating broad adaptation to these 2 different crop structures. Many have widespread distributions e.g. 15 of the focal species have a distribution covering all agricultural regions of Europe (Northern, Central & Southern zones). Three species, corn bunting, serin and tree sparrow are restricted to the Central and Southern zones while another 4 species, Sardinian and fan-tailed warbler, crested and short toed lark are essentially restricted to the Southern zone. The authors consider the focal species identified are suitable for risk assessment in Europe at the zonal level and for further refinement of exposure through studies, i.e. radio-tracking and/or diet analysis, if necessary.

### WE368

#### **Outbreak-based surveillance as tool for assessment of regulation of plant protection products - Example of the rodenticide Bromadiolone in France**

T. Quintaine, ONCFS / Unite Sanitaire de la France; M. Coeurdassier, Université de Franche-Comté / Laboratoire Chrono-environnement; P.J. Berny, VETAGRO-SUP / Toxicology; M. Sage, Wildlife Environment Expertises; A. Decors, ONCFS / SAGIR Network

In France, bromadiolone may be used in agriculture to control water voles populations since 1979. Because of the high risk of unintentional poisonings associated with bromadiolone applications, a monitoring program of wildlife poisoning with bromadiolone has been conducted in a north-eastern French region from 1998 to 2011, where bromadiolone has been regularly extensively used. An outbreak-based monitoring of wildlife mortalities has been conducted by the French Wildlife and Hunting Agency, local Hunters Federation and naturalist associations, associated with a reflexion managed by the local Agricultural administration and the University of Franche-Comté. The SAGIR network took charge of dead animals to diagnose the etiology of death for each collected carcass, based on a necropsy and complementary examinations if necessary, as toxicological analysis. In case of mortalities grouped in space and time, only a part of carcasses were analysed. From 1998 to 2011, 666 fatalities of wild birds and mammals have been reported with a suspicion of intoxication with bromadiolone based on records accompanying the carcass discovery, from which 416 had been confirmed. The confirmed intoxications concerned 17 species of birds of prey and mammals, including endangered species as Red Kite. The evolution of the legislation was followed consequently by a decrease of the quantity of bromadiolone used for treatments. The number of confirmed or suspected cases reported followed this evolution to reach in 2011 only eight cases. This retrospective study is a unique example of collaboration of people with differing interests: hunters, naturalists and farmers. Moreover, it confirms the usefulness of outbreak based surveillance for regulation process, especially for the risk assessment in the context of a post-authorisation to place on market process.

### WE369

#### **Use of dehusking in plant protection product risk assessment for birds and mammals**

M. Hackett, ADAS UK Ltd / Cambridge Environmental Assessments; A. Lawrence, Cambridge Environmental Assessments

Use of seed dehusking as an exposure refinement option for birds and mammals is discussed in EU guidance documents and zonal reviews of risk assessment information. Various criteria are set in EFSA (2009) which must be fulfilled before using dehusking as a quantitative refinement option. However, the use of dehusking as a refinement option is not applied consistently by EFSA nor by member states. Research is available on different aspects of dehusking including species which are confirmed to dehusk, the proportion of seed dehusked during feeding and the level of seed residue reduction achieved during dehusking behaviour of different species. This literature review of the available research on dehusking and feeding behaviour of birds and mammals aims to: Discuss the regulatory situation at EU and national level with regards to acceptability of dehusking as refinement option Identify species for which dehusking is a suitable option for refinement Evaluate and identify seed and spray treatment scenarios where dehusking is relevant for risk assessment Evaluate the suitability of dehusking in relation to different seed types Recommend suitable default values for proportion of seed dehusked and residue reduction achieved during dehusking which can be used in risk assessment for different species Identify species and scenarios for which further research is required.

### WE370

#### **Common vole (*Microtus arvalis*) Ecology and Management: Implications for Risk Assessment of Plant Protection Products**

P. Manson, Cheminova AS European Regulatory Office / Global Regulatory Science; T. Fredericks, Monsanto Company / Agronomic Environmental Assessment Services; R. Barfknecht, E. Bonneris, Bayer CropScience Aktiengesellschaft / BCS AGDnSaETX; J. Jacobs, Federal Research Centre for Cultivated Plants

The common vole (*Microtus arvalis*) is a small herbivorous mammal with a widespread European distribution. Appearing frequently in regulatory risk assessments for plant protection products in the EU, it is the representative small

herbivorous mammal. Due to the conservative nature of the risk assessment for this species, this scenario frequently fails the lower tier long-term risk assessment. This poster describes common vole population dynamics, habitat and food preferences, their pest status within the EU and their use as a focal species in EU risk assessments. A common voles' primary habitat is grassland. Periodic population outbreaks and movement of common voles onto agricultural land (considered secondary habitat) across Europe has resulted in the common vole achieving 'agricultural pest' status in some areas. Movements into secondary habitats occur when the carrying capacities of their primary grassland habitats are exceeded. When movement of common voles occurs early in the crop growing season, significant damage to the crop can result from direct consumption of the crop shoots and leaves. Indirect crop damage is also caused by nest construction and extensive burrowing activity in the field, affecting the development of crop root systems. This can lead to reduced crop yields and crop failure in some cases. Consequently, common vole population management controls are practiced in many countries to prevent common vole populations reaching damaging levels. Common voles have short gestation periods and a high fecundity level that ultimately leads to a high resilience to population disturbance. Population movements into cropped areas are driven by density dependent factors occurring in primary habitats. These specific characteristics of the common vole indicate that the protection level afforded through mammalian risk assessment could be modified without affecting the common voles ecosystem service to the food chain within modified agricultural habitats. For EU risk assessments, it is appropriate to review and modify as required, the small herbivorous mammal scenario. Alternatives including the use of alternative focal species, deriving realistic food intake rates and using reduced assessment factors or a combination of all alternatives, when conducting EU risk assessments is appropriate. Pragmatic modifications to risk assessments are already permitted in certain EU member states. It is reasonable to apply similar approaches across the wider EU.

### WE371

#### **Monitoring the exposure of non-target birds and mammals to anticoagulant rodenticides-a new regulatory tool**

R.F. Shore, Centre for Ecology & Hydrology (NERC); P.A. Henrys, Centre for Ecology and Hydrology; L.A. Walker, Centre for Ecology & Hydrology  
In Britain, the use of second generation anticoagulant rodenticides (SGARs) in open areas is thought to present the greatest risk of exposure in non-target wildlife. Until recently, the most acutely toxic compounds (brodifacoum, flocoumafen, difethiolone) have been restricted to indoor use; open area use has only been permitted for bromadiolone and difenacoum. However, recent regulatory review has determined it is impossible to distinguish between all five SGARs in terms of risk to non-targets, and thus they should be treated identically. It is proposed that authorisations are changed such that all can be used in and around buildings; some compounds may be used in open areas under certain circumstances. The proposed change in authorisation requires implementation of a stewardship scheme designed to enhance best practice in terms of use, and thereby reduce non-target exposure. Such changes in authorisation are likely to alter exposure and associated risk to non-targets. The intention is that overall exposure should be decreased if stewardship is successful, and it is important that the success or otherwise of stewardship is monitored and assessed. The Predatory Bird Monitoring Scheme (PBMS- <http://pbms.ceh.ac.uk/>) has been monitoring liver SGARs in barn owls (*Tyto alba*) annually. This large unique dataset has the potential to provide a baseline against which any future changes in non-target exposure can be measured. We examined this dataset to determine whether, and over what time period, 5-50% changes in exposure could be detected. Change in exposure was defined as a change from baseline levels in annual mean barn owl liver SGAR concentrations. Lack of normality in the distribution of the residue data for individual compounds and summed SGARs ( $\Sigma$ SGAR) meant it was necessary to split the data into two groups for each compound - "low" concentrations: < 0.1 µg/g and "high" concentrations: > 0.1 µg/g wet wt.; "high concentrations" can be considered relevant in terms of acute toxicity. We found that, for both data sets, we could detect changes of 10-20% from baseline concentrations by analysing between 50 and 100 birds annually for between 1 and 4 years. Power was always  $\geq 70\%$ . Such monitoring can be used to set targets for stewardship outcomes and as a regulatory trigger for implementing further changes to authorisations if necessary.

### WE372

#### **Measured residues on maize foliage for use in bird and mammal risk assessment**

R. Murfitt, Syngenta Ltd / Environmental Safety; M. Foudoulakis, Dow Agrosciences / RSRA ERS; M. Ebeling, Bayer CropScience AG EnSa-ETX-TV / Environmental Safety Ecotoxicology; T.B. Fredricks, Monsanto Company / Zoology; K. Guth, BASF SE / Ecotoxicology; K. Brugger, DuPont Crop Protection  
In mammal risk assessment for plant protection products in the EU according to Tier 1 of the EFSA Guidance Document on Risk Assessment for birds and mammals (2009), small herbivorous mammals are considered to consume maize leaves at early growth stages (BBCH 10-29). However, the initial residue for maize leaves in this assessment is based upon Residue per Unit Dose (RUD) values for grasses and cereals which in turn are derived from industry field data on grasses and cereals, excluding any maize trials (Appendix 18, PPR Panel Scientific Opinion on the Science behind the Guidance Document on Risk Assessment for birds and

mammals, 2008). Since maize has quite a different growth habit from grasses and small-grain cereals like wheat and barley, it is appropriate to consider residues on this crop separately in order to determine whether they are significantly different. Therefore, in order to determine a more realistic estimate of initial residue and hence Residue per Unit Dose for maize, a large dataset of residue field trials from industry have been compiled and mean and 90<sup>th</sup> percentile RUD values calculated. These will be presented in the poster and compared to the current values for grasses and cereals. The proposal is that maize foliage RUD's, if different from those for grasses and cereals, should be used in Tier 1 risk assessment for small herbivorous mammals at BBCH 10-29.

### WE373

#### **Extrapolated LD50 values from limit dose tests for mammals**

M. Foudoulakis, Dow Agrosciences / RSRA ERS; E. Bonneris, Bayer CropScience Aktiengesellschaft / BCS AGDnSaETX; L. Lothar Dising, Bayer CropScience AG; T. Fredricks, Monsanto Company; K. Guth, BASF SE / Ecotoxicology; P.J. Edwards, Central Product Safety Dept; K. Brugger, DuPont Crop Protection  
In the EFSA bird and mammal guidance document (EFSA, 2009) the use of extrapolated LD<sub>50</sub> values from avian limit dose tests are proposed, in cases where there is no mortality or a single mortality in an avian LD<sub>50</sub> limit dose study. The proposed extrapolation factors assume an average probit slope generated from a large sample of pesticides tested in the bobwhite quail and mallard duck. The method of calculating an extrapolated LD<sub>50</sub> from a limit dose could be equally applied to mammals. The aim of this work is to propose extrapolation factors for LD<sub>50</sub> values from limit dose tests with mammals. The database consists of a significant number of acute toxicity records of dose-response toxicity studies generated for registration purposes on rat and mice with a variety of compounds. Analysis was performed as described in the Appendix 5 of the Scientific Opinion behind the Guidance Document on risk assessment for birds and mammals (EFSA 2008) where the extrapolation is carried out assuming a 50% binomial probability bound that mortality could have occurred but had simply been missed by chance in the test. The outcome of this work contains estimated mammalian LD<sub>50</sub> extrapolation factors per number of animals tested at the limit dose.

### WE374

#### **Reproductive risk assessment for birds: LD50/10 vs. dietary NOAEL for evaluation of parental effects**

M. Foudoulakis, Dow Agrosciences / RSRA ERS; M. Ebeling, Bayer CropScience AG EnSa-ETX-TV / Environmental Safety Ecotoxicology; D. Sprenger, BASF SE; R. Murfitt, Syngenta Ltd / Environmental Safety; T. Fredricks, Monsanto Company; K. Brugger, DuPont Crop Protection

In the environmental risk assessment for plant protection products in the EU according to the EFSA GD (2009), the LD<sub>50</sub>/10 is used in the reproductive assessment for birds to take account of the possibility of reproductive impairment due to sublethal parental effects e.g. on pair formation or nest-building, not covered in the reproduction study. The objective of this work was to evaluate the use of a short-term dietary NOAEL as refinement for the acute LD<sub>50</sub>/10 in the reproductive risk assessment for birds. The rationale behind this approach is to overcome the need to conduct reproductive assessment based on the LD<sub>50</sub> value generated in the artificial acute test design with oral gavage. In order to determine the relation between the avian endpoints a significant dataset of avian laboratory studies have been compiled from industry and the LD<sub>50</sub>/10 was compared with the NOAEL from the dietary and reproduction studies. These studies represent molecules from a variety of toxicological profiles and mode of actions. For these compounds, the relevant regulatory LD<sub>50</sub> (geomean if appropriate for multiple species) was extracted and used to establish one LD<sub>50</sub>/10 per compound for the comparison to dietary toxicity values. Additionally the NOAEL from the short-term dietary and the reproduction studies (in mg/kg bw/d) were also presented in a tabular form. From these dietary toxicity data, one 5-d dietary NOAEL (lowest) and one avian repro NOAEL (lowest) were extracted and used in the comparison to the acute oral LD<sub>50</sub>/10 for the respective compound. Evaluation indicates that the 5-d dietary NOAEL may be employed as a surrogate for the LD<sub>50</sub>/10 and the next lowest endpoint would likely be the avian reproduction study NOAEL. Therefore it is reasonable to apply a similar approach for avian long term risk assessment according to EFSA (2009), where dietary toxicity data are already available.

### WE375

#### **Accumulation and temporal trends of organohalogen contaminants in finless porpoises (*Neophocaena asiaeorientalis*) collected from Korean coastal waters between 2003 and 2010**

y. jeong, Hanyang University; E. Kim, W. Jeong, A. Shen, Hanyang University; Y. An, Research Institute (CRI), National Fisheries Research and Development Institute; S. Choi; H. Moon, Hanyang University / Marine Sciences and Convergent Technology

Limited information is currently available on temporal trends of persistent organic pollutants (POPs) in Korean coastal waters. In our study, the concentrations of organochlorine compounds (OCs) and polybrominated diphenyl ethers (PBDEs) in 77 blubbers of finless porpoise (*Neophocaena asiaeorientalis*) were determined to evaluate the contamination status and temporal trends of POPs between 2003 and 2010. The concentrations of OCs (PCBs, DDTs, HCHs, and CHLs) and PBDEs in porpoise blubbers collected in 2010 ranged from 51 to 3200 ng/g lipid weight (lw)

for PCBs, 240 to 10000 ng/g lw for DDTs, *p,p'*-DDE showed the highest contribution (mean: 41%), followed by *p,p'*-DDT, *p,p'*-DDD, *o,p'*-DDT and PCB 153. The predominant congener of PBDEs was BDE 47, which accounted for 58% of total PBDEs. In order to assess the temporal trends of POPs during the period of seven years, we employed the concentrations of PCBs, OCPs and PBDEs in the same species collected in 2003 from a previous study. The total concentrations of PCBs, DDTs, HCHs, CHLs and PBDEs significantly ( $p < 0.0001$ ) decreased between 2003 and 2010. Almost 90% of HCH concentrations during both years decreased, indicating faster elimination compared to other POPs. The relatively lowest decreasing rate was found for PCBs (53%) and PBDEs (60%), compared to other chemicals such as DDTs (70%) and CHLs (69%), because PCBs and PBDEs have on-going source in coastal environment of Korea. Our results suggest that the effectiveness of regulation on the POPs in Korea has reached to the marine mammals, which occupy the higher trophic level in marine food web. To our knowledge, this is the first report to assess the temporal trends of OCs and PBDEs using marine mammals from Korean coastal waters. Keywords POPs, finless porpoise, temporal trend, marine food web

## Risk assessment, risk management and mitigation for pesticides: from regulation to public perception (P)

### WE376

#### Minimum detectable differences (MDD's) in mesocosm studies: The importance of pre-treatment management and appropriate sampling techniques for insecticides

A. Blakey, Cambridge Environmental Assessments; S. Taylor; S. Priestly, Cambridge Environmental Assessments

The Aquatic Guidance Document (EFSA, 2013) makes a number of recommendations for aquatic mesocosm studies including the reporting of Minimum Detectable Difference (MDD) values alongside No Observed Effect Concentrations (NOEC). In addition, it is recommended that each study contain at least 8 different sensitive and vulnerable groups for which robust statistical evaluation is possible in order to be able to derive robust the Ecotoxicological Threshold Option (ETO) or the Ecological Recovery Option (ERO) –Regulatory Acceptable Concentrations. Critical to the derivation of robust endpoints is the appropriate establishment of replicate mesocosms with diverse and numerous populations and communities known to be sensitive and vulnerable to the effects of the pesticide of interest. Furthermore, in-life sampling techniques must be appropriate for the collection of the exposed organisms at an abundance sufficient to ensure reasonable MDD values can be derived from the data, whilst also ensuring that all ecological niches are sampled. Here we will show the evolution of study design focussing on the pre-treatment phase and in-life sampling techniques at Cambridge Environmental Assessments (CEA) whilst drawing on examples from a number of recent mesocosm studies in order to demonstrate how robust data may be better derived from studies with insecticides.

### WE377

#### The Minimum Detectable Difference (2): Appropriate experimental design and endpoint selection for algae in mesocosm studies

F. Pickering, Cambridge Environmental Assessments; S. Taylor; A. Arenas-Sanchez, S. Priestly, Cambridge Environmental Assessments

Algal communities have a very dynamic nature and are in a constant state of flux whilst community interactions are poorly understood. They are sensitive to a number of different variables which makes it difficult to pinpoint true dose related effects when evaluating responses following exposure to pesticides. Therefore, it is tempting to speculate that the ecological relevance of endpoints for phytoplankton from mesocosm studies based on effects at the species level could be considered to be over-conservative due to the natural variation. In contrast, recent guidance on the conduct and interpretation of mesocosm tests highlights the importance of using the most appropriate aquatic communities for the chemical being investigated. In addition, it is equally the selection of appropriate measurement endpoints and ecological evaluations is critical to the derivation of powerful statistical results with reasonable Minimum Detectable Difference (MDD) values. Here we will show the evolution of study design and endpoint selection for algae in regulatory mesocosm tests using examples drawn from recent state of the art studies with herbicides. We will provide an analysis of the available data for algae (phytoplankton and periphyton) comparing the respective reliability of the data generated at various taxonomic levels in being able to robustly measure effects and recovery in freshwater mesocosms following exposure of algal communities to pesticides. We will also provide recommendations for further work in order to still improve the robustness of the endpoints for use in regulatory risk assessment.

### WE378

#### Toxicity of the fungicide ketoconazole to freshwater microalgal communities

A. Arrhenius, M. Andersson, University of Gothenburg / Department of Biological and Environmental Sciences; L. Edler, WEAQ AB; T. Porsbring; T. Backhaus, University of Gothenburg / Department of Biological and Environmental Sciences Antimycotic pharmaceuticals are widely used for treating fungal infections in humans and animals. They enter the aquatic environment either after passage through the body, or after being rinsed off if they are topically applied. However,

substantial knowledge gaps currently hamper a proper environmental risk assessment of the individual antimycotics and their mixtures for marine and freshwater environments. Clotrimazole, a marine priority pollutant, affected sterol composition of marine microalgal communities already at 50 pmol/L which indicates effects already at environmental concentrations. In the present study we focus on ketoconazole (also an azole fungicide) and toxicity to freshwater microalgal communities. A concentration response curve was first established using pigment profiles (HPLC) as endpoint which resulted in an EC50 of around 1 micromol/L. During autumn 2014 we repeated the study but focused on the lower concentration range from 0.0001 to 1 micromol/L. Results on chlorophyll *a* show similar patterns as in the initial study. The experiments were finished during autumn 2014 and are currently under final evaluation and sterol analysis, species determinations and analytical confirmation of exposure concentrations are currently evaluated. The work is performed within the Swedish Formas-funded project "Aquatic Environmental Risk Assessment of Antimycotics".

### WE379

#### Species specific differences in sensitivity to prochloraz induced synergy of $\alpha$ -cypermethrin toxicity

N. Cedergreen, K. Dalhoff, V. Serrat, University of Copenhagen / Department of Plant and Environmental Sciences

Azole fungicides are known to enhance the effect of other xenobiotics, there among the pyrethroid insecticides. Field studies have also shown azole fungicides to be present more or less continuously during the growing season. The concentrations are low, however, rarely exceeding 10 µg/L and are mostly lower than 1 µg/L. The question is whether these low azole concentrations do also enhance the effect of pyrethroids? And whether there is a large difference between species in their sensitivity to synergistic compounds? In this study we test the effect of a five hour  $\alpha$ -cypermethrin pulse at three concentrations over seven days in the continuous presence of the azole prochloraz at 0, 1, 10, 50 and 100 µg/L. The setup was carried out on the three aquatic invertebrate species: *Daphnia magna*, *Hyalella acteca* and *Chironomus riparius*. The results showed that six days after a 1 µg/L  $\alpha$ -cypermethrin exposure, concentrations as low as 1 µg/L prochloraz increased mortality from the app. 15% control mortality to 100% in *Daphnia magna*. Contrary to *D. magna* where the prochloraz concentrations alone had no effect on mortality (6 day LC50 for *D. magna* was 4476 µg prochloraz/L), both *H. acteca* and *C. riparius* were very sensitive to prochloraz showing 6 day LC50-values of 3.33 and 41.4 µg prochloraz/L. Accounting for the prochloraz toxicity in itself, synergy in relation to independent action predictions, was also observed for *H. acteca* and *C. riparius*. Though these data are preliminary, they indicate that azole synergy does take place also at quite low and realistic concentrations, and that species specific differences in sensitivities to an azole as prochloraz are quite larger with EC50 values varying more than 1000-fold.

### WE380

#### Future challenges in sediment toxicity testing for the risk assessment of plant protection products

D. Faber, E. Bruns, Bayer CropScience AG / BCS D ETX Ecotoxicology Sediment toxicity is gaining an increasing awareness within the scientific community. In 2015 a scientific opinion on environmental risk assessment (ERA) for sediment organisms will be published by the European Food Safety Authority (EFSA)<sup>1</sup>. This scientific opinion will be of high interest because so far, only tier 1 RA for sediment organisms is addressed in the existing aquatic guidance document published in 2013 by EFSA<sup>2</sup>. The number of currently available standardized and validated test guidelines under the umbrella of OECD is limited. Aquatic invertebrates are covered by the OECD technical guidelines (TGs) 218/219/233 for chironomids (*Chironomus riparius*), representing acute, chronic and full life-cycle tests, respectively, and the OECD TG 225 using the oligochaete *Lumbriculus variegatus* in a 21-day chronic test. Aquatic macrophytes are covered by *Myriophyllum spicatum* (OECD TG 239). In North America the question of sediment toxicity is handled differently as reflected by the ASTM and US-EPA guidelines. In general a higher number of test methods with sediment organisms is available (e.g. *Hyalella azteca*, *Chironomus dilutus*, *Daphnia magna*) in the USA and Canada. Furthermore these guidelines are developed under a different scope as compared to the OECD TGs (e.g. use of aged spiked sediment under flow-through conditions vs. use of "freshly" spiked sediment in a static system). Another major difference is the use of natural sediment in ASTM and US-EPA guidelines instead of artificial sediment in OECD TGs. The resulting discrepancies between Europe and North America are influencing the potential use of all existing guidelines within one RA approach. The communication therefore will analyze pros and cons of sediment toxicity test designs (e.g. static vs. flow-through; natural vs. artificial sediment) described in guidelines available in Europe and North America. Stakeholders should be aware that not every standardized and validated method is giving comparable endpoints. We would like to address also the consequences of the different testing approaches as well as the resulting possibilities for the appropriate use within one ERA. <sup>1</sup>"Scientific Opinion of the PPR Panel on the effect assessment for pesticides on sediment organisms in edge-of-field surface waters". <sup>2</sup>"Guidance on tiered RA for plant protection products for aquatic organisms in edge-of-field surface waters" EFSA, 2013.

### WE381

### **Influence of crop management practices on zonal avian risk assessment of plant protection products. Case of study: a systemic pesticide applied as seed treatment on sugar beet**

A. Fandiño, INIA National Institute for Agricultural and Food Research and Technology / Technical Directorate for Evaluation of Plant Varieties and Plant Protection Products; E. Prados, INIA; J.L. Alonso-Prados, INIA National Institute for Agricultural and Food Research and Technology / Technical Directorate for Evaluation of Plant Varieties and Plant Protection Products

Regulation 1107/2009 includes the concept of the zonal evaluation, and the subsequent mutual recognition of authorizations in order to guarantee the commercialization of Plant Protection Products (PPP) in the EU and avoid duplication of work. The risk assessment of plant protection products on birds and mammals is currently conducted using the Guidance document of European Food Safety Authority (EFSA) on Birds & Mammals (2009). If the uniform principles are not met at the first tier risk assessment steps, a list of refinement options are described in this guidance including i) the identification of focal species, ii) the proportion of diet (PD) of these species taken from treated areas iii) the residue levels of pesticide in this diet and iv) the time that focal species spend feeding in treated area (PT). As long as these parameters need to be refined, the zonal harmonization between European zones is becoming more difficult because they will depend on specific agro-climatic conditions. This is more challenging for seed treatment applications because its evaluation is considered under an inter-zonal scheme. In this work, we present the main difficulties identified to harmonise zonal evaluations for seed treatments using as example a hypothetical systemic pesticide applied on sugar beet seeds. The results show the time of sowing the sugar beet (spring or autumn depending on geographical situation) and the associated crop management practices were critical for establishing the worst-case exposure scenario for avian risk assessment and the ecological parameters (PD and PT) of focal species. In conclusion, together with information on ecological data and residues levels of pesticide (which are currently being investigated by EFSA), it is also necessary to characterize the specific agronomical conditions of each crop at member state level before to set out procedures for zonal evaluation.

### **WE382**

#### **Are ecotoxicological tests with plant protection products for C-and N-mineralization sufficient to protect soil functioning?**

E. Kohlschmid, Agroscope / Institute for Plant Production Sciences IPS; K. Lautenschlager, Agroscope Changins-Wädenswil; A. Aldrich, Research Station Agroscope ACW / Ecotoxicology; O. Daniel, Agroscope / Institute for Plant Production Sciences IPS

Soil functioning depends on many different microbial activities and effects. Fungi and Bacteria are not only key players in soils for the decomposition and mineralization of organic compounds (including agrochemicals and xenobiotics), but also synthesize organic compounds (e.g. antibiotics, gums), immobilize nutrients, contribute to soil aggregation or serve as nutrient source for the grazing microfauna. Furthermore mycorrhizal fungal species mediate the transport of water and ions from soil to plant roots or facilitate plant/plant exchanges of small organic compounds and nutrients. Many other important functions such as the regulation of water and ion movement through plants or the regulation of the photosynthetic rate are facilitated by mycorrhizal fungal species. For the registration of plant protection products (PPP), sufficient data must be provided to evaluate the impact of active substances on soil microbial activity in terms of nitrogen transformation and carbon mineralization. The latter is not required anymore according to the new data requirements of the commission regulation from 2013. The question arises if N-mineralization alone gives an adequate answer if soil functioning is affected by PPP. We have analyzed data from active ingredients with fungicidal activity for C- and N-mineralization of the Swiss ecotoxicological database (holding data on formulations and active ingredients). Results are presented and further needs for risk evaluation on microorganisms are discussed with respect to all microbial functions mentioned above.

### **WE383**

#### **Is it safe to recycle home & garden pesticide containers?**

C. Ramwell; S. Beulke, FERA / Food and Environmental Safety Programme; K. Tiede, Food and Environment Research Agency; S. Monteiro, APC Ltd; M. Kennedy, E. Bradley, The Food and Environment Research Agency

The increasing use of ready-to-use (RTUs) pesticide products and the need for recycling to increase means that government advice regarding the disposal of home and garden pesticide containers – rinse and put in the ‘black bin’ – may no longer be appropriate. The aim of our project was to assess the risk to humans and the environment of disposing of used, amateur pesticide containers via recycling, and to compare the risks identified with those arising from landfill and incineration which would result from disposal via a dustbin. The study generated a quantitative model comparing the predicted human or environmental exposure to an exposure threshold to assess the likelihood of an adverse risk occurring. The environmental risk associated with the disposal of residue in part-filled bottles and rinsate from empty bottles was predicted to be below the trigger threshold for four of the five compounds tested. The calculations indicated a moderate risk for fish and algae arising, with and without rinsing, for the remaining compound. Human exposure associated with the disposal of RTU bottles was consistently below the acceptable operator exposure limit (AOEL). Human exposure associated with the disposal of

concentrate bottles was consistently below the AOEL for all disposal routes, as long as there was no spillage of partially-filled bottles. UK policy has now been amended to allow the recycling of empty RTU home and garden pesticide containers.

### **WE384**

#### **Pesticides in Swiss surface waters - The gap between risk assessment and monitoring**

B. Fulda, Agroscope; A. Aldrich, Research Station Agroscope ACW / Ecotoxicology; R. Kasteel, M. Balmer, T. Poiger, Agroscope

The transport of pesticides from agricultural areas to adjacent non-target environments, in particular surface water systems, is estimated for the ecotoxicological risk assessment prior to the registration of pesticides. In Switzerland the pesticide concentrations in surface waters are predicted by environmental realistic worst-case models, considering pesticide leaching via drainage, surface runoff, and spray drift. The entry via drainage and runoff is simulated with EXPOSIT 3.01 (German Federal Environment Agency, UBA) whereas drift is calculated using the basic drift values after Rautmann et al. (1999). These models are designed to be “conservative”, representing the edge of field and should therefore result in higher predicted pesticide concentrations (PEC) than would actually occur in the environment. A comparison between the PEC of a pesticide and the measured environmental concentrations (MEC) from field monitoring studies can be useful to ascertain potential model deficiencies and provide a valuable feedback loop to the registration process. In this study we compared a large set of Swiss surface water monitoring data from 2005 – 2012, covering a variety of registered plant protection products (PPP), with PEC values derived during the Swiss regulatory risk assessment. In a first assessment, only few cases of PEC exceedance were found, concerning only few substances and sampling locations. However, the ratios between PEC and MEC were highly dependent on various critical factors as for example the assumed entry pathway, the selection of the appropriate PEC-scenario from the multiple authorized indications or inclusion of mitigation options like no-spray buffers zones. In addition, the validity of results is also restricted by limitations in the monitoring data for example partially low sample frequency, inadequate sampling approaches to capture peak concentrations and a high fractions of non-detects that may also be associated with lack of application in the catchment area or in the relevant time period. The results of such comparisons of exposure model vs. monitoring data must therefore be interpreted with caution.

### **WE385**

#### **The Swiss re-evaluation process of authorised plant protection products: Outcome of the ecotoxicological risk assessment**

A. Aldrich, Research Station Agroscope ACW / Ecotoxicology; R. Gauch; E. Kohlschmid, Agroscope / Institute for Plant Production Sciences IPS; K. Lautenschlager, D. Ruf, Agroscope Changins-Wädenswil; M. Plath, O. Daniel, Agroscope / Institute for Plant Production Sciences IPS; S. Knauer, The ecotoxicological evaluation procedure of plant protection products (PPP) in Switzerland is analogous to the EU. In total about 2000 products and 400 active substances are authorized in Switzerland. In 2010 a re-evaluation process of authorized PPP started in Switzerland. Current scientific knowledge and the data obtained during the EU re-registration process of active substances are taken into account. The outcome of the re-evaluation process may be altered conditions of use or new risk mitigation measures for authorized PPP. The evaluation of all authorized PPPs containing the same active substance follows a complex procedure and lasts about 1.5 years. Up to now, about 550 PPP with 50 different active substances have been re-evaluated. The current presentation focusses on the methodological approaches and outcome of the ecotoxicological risk assessments performed during the Swiss re-evaluation process. Even though only one substance is evaluated at a time, the number of scenarios that need to be evaluated is substantial as the same active substance can be formulated in several PPP and each PPP may be authorized for several different uses. In order to deal with the extensive workload a pragmatic worst-case approach has been established, which can be refined when needed. Although not finished yet, the re-evaluation process has led to an optimization of the available means, to an elaboration of new risk mitigation measures and overall to an increased protection level for the environment. In the poster the current outcome of the Swiss re-evaluation process regarding the ecotoxicological risk assessment will be presented and it will be looked into how this can be illustrated in order to communicate the achievements and increase the transparency of the process.

### **WE386**

#### **Ecosystem Services Analysis of 1,3-D Use in Integrated Pest Management Strategies in Tomato Production in Italy**

N. Eury, S. Deacon, ENVIRON UK Ltd; A. Alix, Dow Agrosiences / Risk Management; E. Tescari, Dow Agrosiences; A. Bartram, Astrazeneca UK Ltd; P. Burston, ENVIRON; M. Rockel, ENVIRON International Corp.; J. Nicolette, ENVIRON International Corporation

This is a case study addressing the use of the soil fumigant 1,3-dichloropropene (1,3-D) within integrated pest management strategies (IPM) for the cultivation of fresh tomatoes in southern Italy. Food production is both economically and culturally important to European farmers, particularly in Italy where farmers grow flavoured tomatoes with passion and pride. Growers rely on pesticides for crop

protection, the potential impact of which is often questioned. A new dossier is being submitted in 2015 to address the European Food Safety Authority (EFSA) concerns relating to product purity and risks to air, groundwater and some soil organisms. Since the non-approval of 1,3-D in 2011, several member states have granted temporary emergency use derogations following requests from farmers. These derogations reiterate the fundamental need for an effective nematicide to promote the efficient protection of high value crops in Europe, such as the tomato. This case study can be used to inform pesticide regulation at member state level where an ecosystem services (ES) approach can inform risk and integrated pest management (IPM) decisions under the European Plant Protection Products Regulation 1107/2009 and the Sustainable Use Directive 2009/128/EC. The *sustainable use* of pesticides calls for a holistic approach to be taken in decision making. ES analysis of 1,3-D use in Italian tomato cultivation was reported in 2013 (and at SETAC Glasgow 2013). This case study represents further analysis of the use of 1,3-D as part of an IPM strategy using field trial data from Dow AgroSciences' IPM studies. The findings will be used in support of the 1,3-D dossier submission to demonstrate holistic assessment and its usefulness in informing regulatory decisions.

### WE387

#### **Residual Characteristics and Estimated Daily Intakes of Dimethomorph and Fludioxonil in Shallot**

J. Kim, H. Noh, J. Lee, H. Park, H. Jeong, M. Jin, Chungbuk National University; C. Kwon, Y. Son, Ministry of Food and Drug Safety; K. Kyung, Chungbuk National University

This study was performed to investigate residual characteristics and calculate estimated daily intakes (EDIs) of dimethomorph and fludioxonil in shallot. Dimethomorph (25% WP) and fludioxonil (20% SC) were diluted 1,000, and 2,000 times, respectively and the diluted solutions were sprayed onto shallot. Treatment consisted of three test plots; twice spraying 7 and 14 days (T-1) or 3 and 7 days (T-2) before harvest and three times spraying 7, 14 and 21 days before harvest (T-3). Samples were collected from three test plots at pre-arranged harvest day. Residues of the test pesticides in the crop were quantified with an HPLC-DAD for dimethomorph and a GC-NPD for fludioxonil. Limits of detection (LODs) of dimethomorph and fludioxonil were 0.02 and 0.01 mg/kg, respectively. Recoveries at 10 and 50 times of the LODs of the test pesticides were 78.1-88.4 and 97.0-103.2%, respectively. Residual concentrations expressed as the highest residue were decreased from 2.03 (T-1), 2.38 (T-2) and 2.09 mg/kg (T-3) at day 0 to 0.18 (T-1), 1.63 (T-2) and 0.22 mg/kg (T-3) at harvest in case of dimethomorph, whereas decreased from 1.13 (T-1), 1.57 (T-2) and 1.24 mg/kg (T-3) at day 0 to 0.03 (T-1), 0.75 (T-2) and 0.05 mg/kg (T-3) at harvest in case of fludioxonil. These results represented that the test pesticides were quickly dissipated from the crop and higher residue were found in the treatment closer to harvest day. The EDIs of the pesticides were less than 0.3% of their acceptable daily intakes.

### WE388

#### **Effect of Spraying Time on Kresoxim-methyl Residue in Shallot and Young Chinese Cabbage**

H. Park, H. Noh, J. Lee, J. Kim, H. Jeong, M. Jin, Chungbuk National University; C. Kwon, Y. Son, Ministry of Food and Drug Safety; K. Kyung, Chungbuk National University

In order to investigate the effect of spraying times on kresoxim-methyl residue in shallot and young Chinese cabbage, the test pesticide (50% WG) was diluted 3,000 times and sprayed onto the test crops growing three test plots; twice spraying 7 and 14 days (T-1) or 3 and 7 days (T-2) before harvest and three times spraying 7, 14 and 21 days before harvest (T-3). After harvest, kresoxim-methyl residues in the crops from three treatment plots were analyzed with a GLC-NPD. Limit of detection (LOD) was 0.01 mg/kg. Recoveries at two levels, 10 and 50 times of the LOD, ranged from 96.4 to 101.5% in shallot and from 78.0 to 84.4% in young Chinese cabbage. Amount of the test pesticide residue was highest in T-2, compared with T-1 and T-3. This result indicated that major factor affecting residue level of the pesticide was not spraying time but spraying day close to harvest.

### WE389

#### **Risk Assessment of the Exposure of Workers to the Insecticide Imidacloprid during Application in Apple Orchard by Speed Sprayer**

J. Lee, H. Noh, H. Park, J. Kim, H. Jeong, M. Jin, Chungbuk National University; E. Kim, Seoul National University; J. Kim, Seoul National University / Department of Agricultural Biotechnology; K. Park, National Academy of Agricultural Science; K. Kyung, Chungbuk National University

This study was carried out to assess exposure and calculate margin of safety (MOS) of imidacloprid commercial product (5% WP) using a whole body dosimetry (WBD) technique during application with a speed sprayer in apple orchards. Pesticide application was done in ten apple orchards by ten operators. Operators put on disposable working clothes and carried the personal air pump with fiber glass filter in IOM sampler which set up flow rate at 120 L/hr during application. Samples were collected just after pesticide spraying. Instrumental limit of quantitation of a high performance liquid chromatograph with diode array detector was 0.05 mg/kg. Recoveries in the matrix, such as fiber glass filter, washing solution for hands and gloves, gauze for face and neck, and outer clothes, ranged from 81.2 to 114.7%. Exposure rates were calculated by comparing exposure amount to application amount of active ingredient in total spraying pesticide.

Amounts of exposure in gloves and hands were 0.00371% and in case of arms, body and hip (total amount of front and back) and legs were 0.0021, 0.00266 and 0.00213%, respectively. Inhalation exposures were less than 0.00001%. Total exposures including all the body parts and inhalation were less than 0.011%. Risk assessment was carried out by calculating MOS. The MOS in this experiment was more than 1, indicating a low possibility of risk.

### WE390

#### **Pesticide residues related risk on human and environment in Turkey**

E. CAMCI, Adnan Menderes University / Faculty of Agriculture Lab Environmental Toxicology; M. Yalçın, Adnan Menderes University / Faculty of Agriculture; C. Turgut, ADU; A. Gavcar, Adnan Menderes University / Faculty of Agriculture Lab Environmental Toxicology; S. Mermer, Fac. of Agriculture Lab Env Tox

Various diseases in humans are occurred by the increased industrialization, people life style who migrated to the city with the progress of science and technology, working life, being away from nature, formation of exclusive natural products consumption habits. Every year due to food insecurity in the world, millions of people lose their lives. Therefore in this study to explore people's consumption habits and ideas about how reliable the food they consume, 59 questions were asked to 216 consumers under 6 groups. 65% of these consumers were female, 35% were male. As a result of received responses, it was observed that 69% of the consumers about food safety, 58% about pesticide residues on vegetables and cereals, 49% about salmonella bacteria or listeri bacteria on cheese, are quite concerned. For this reason public officials should follow every step from farm to meal, they should allow to sell after being sure that packaging and transportation processes are controlled. For the improvement of consumer awareness; what are the food risks, which topics should be taken into account, what kind of consumption habits do people have and so on should be investigated.

### WE391

#### **Alterations on synapsin immunostaining in mushroom bodies of africanized honeybees *Apis mellifera* (Hymenoptera, Apidae) exposed to sublethal dose of Thiamethoxam.**

T. Roat, Biology; A. Catae, São Paulo State University UNESP / Biology; P. Friol, São Paulo State University UNESP; P. Cintra-Socolowski, São Paulo State University UNESP / Biology; R. Nocelli, Federal University of Sao Carlos UFSCAR Araras; P. Nunes, São Paulo State University UNESP / Biology; O. Malaspina, Universidade Estadual Paulista UNESP

Honeybees (*Apis mellifera* L., 1758) are important pollinating insects giving to this specie a great agronomic, environmental and economic relevance. However the reduction in the number of pollinators, especially bee species, may threat food security and ecosystem integrity. Many stress factors acting alone or together, can weaken the colony including the decreased availability of resources due to the degradation and fragmentation of honeybee habitat, pathogens and parasites, beekeeping management, and the use of chemical pesticides on crop.

Thiamethoxam is a neurotoxic insecticide, acting as an agonist of acetylcholine and is used in sugarcane cultures, which are large crops in Sao Paulo State. Therefore, this study aimed to investigate how the brain of these insects reacts to the intoxication by sublethal dose LD<sub>50/100</sub> of thiamethoxam. For this, we analyzed possible changes in synaptic pattern in the mushroom bodies of africanized honeybees by immunostaining of the protein synapsin. Brains of foragers bees exposed to the sublethal dose (0.0027 ng of thiamethoxam/ bee) for until 8 days were incubated with a monoclonal antibody against the protein synapsin (1 SYNORF ANTI) conjugated to CY5 (secondary antibody) and it was used DAPI, for nuclei staining. Using the software LAS-AF with the Confocal Laser Scanning Microscope Leica TCS SP5-II, it was possible to measure the intensity of emitted fluorescence in the areas of the mushroom bodies. The synapsin labeling was more evident in the mushroom bodies of bees exposed to the sublethal dose specifically in the regions of glia, compared with the control group. Thus, the sublethal dose of the insecticide thiamethoxam intensified synapsin immunostaining, suggesting an increased release of neurotransmitters, which may be linked to neurotoxicity, and overexcitation. These results provided information about which brain structures are affected by thiamethoxam, which suggest possible physiological and behavioral consequences that such exposure may cause in the insect that can affect the intra-colonial relations. Financial Support: Fapesp (2012/13370-8)

### WE392

#### **Monitoring of pesticides in groundwater - First steps of a SETAC group to develop a guidance**

A. Gimsing, The Danish Environmental Protection Agency / Pesticides and Gentechnology; W. Tüting, German Federal Office of Consumer Protection and Food Safety (BVL); A. Boivin, ANSES

The SETAC Environmental Monitoring Advisory Group of Pesticides (EMAG-Pest) deals with post-registration studies and monitoring data for an evaluation of environmental effects of Plant Protection Products. It is structured into four working groups: Terrestrial vertebrates, terrestrial invertebrates including foliar and soil organisms, surface water and aquatic organisms and ground water. The aim of the groundwater (GW) working group is to develop a guidance on groundwater monitoring for regulatory purposes. The experts' first outcome on the discussions regarding the following four topics will be presented. Specific

Monitoring data in regulatory context: Monitoring data can be used in the regulation of pesticides, but use of such data is not straight forward. Key question: When should a groundwater study be triggered/recommended and what questions should a monitoring study answer? Monitoring and modelling: When monitoring studies are available, they are always compared with modelling results (FOCUS or local modelling). Key question: Could a groundwater monitoring be used as the highest-tier study and supersede a modelling study? Limitations and strengths of both studies. Groundwater Monitoring “good practices”: The design of a monitoring study and the quality of the data are key to generate valuable monitoring results. Key question: How should a monitoring study be designed so that data can be used for regulatory purposes (demonstrating relevance/representativity of data, comparison with protection goals)? Interpretation of GW monitoring data / Representativity of GW monitoring: How to interpret/use monitoring data and the representativity of monitoring are probably the two main recurrent questions associated with monitoring. These two questions are raised for both compound specific monitoring studies and for public monitoring programmes which may be available. Recommendations are needed on how results should be used and to define what the monitoring data should represent/cover for both types of monitoring studies/programmes. How can these two types of monitoring complement each other? Key question: How to assess to what extent monitoring sites used in a study are representative for a product’s usage area in terms of leaching vulnerability and demonstrating safe use?

### WE393

#### **Residual Characteristics of Fungicide Dimethomorph, Fludioxonil, and Kresoxim-methyl in Water Dropwort and Risk Assessment**

H. Noh, J. Lee, H. Park, J. Kim, H. Jeong, M. Jin, Chungbuk National University; C. Kwon, Y. Son, Ministry of Food and Drug Safety; K. Kyung, Chungbuk National University

This study was carried out to investigate residual characteristics of dimethomorph, fludioxonil, and kresoxim-methyl and evaluate their estimated daily intakes (EDIs) in water dropwort. The test pesticides were diluted 1,000 for dimethomorph (25% WP), 2,000 for fludioxonil (20% SC) and 3,000 times for kresoxim-methyl (50% WG) and then the diluted solutions for spraying were treated onto the test crop. Treatments consisted of twice spraying 7 and 14 days (T-1) or 3 and 7 days (T-2) before harvest and three times spraying 7, 14 and 21 days before harvest (T-3). Recoveries of the test pesticides ranged from 90.4 to 110.5%. The residue levels were higher in case of T-2 than the other treatments, irrespective of spraying times. Dissipation rates of the pesticides at harvest were lowest in T-2, suggesting that time for dissipation was shorter in T-2 than T-1 and T-3. The EDIs of the test pesticides calculated using the highest residues in water dropwort were less than 0.1% of their acceptable daily intakes.

### WE394

#### **Residual Pattern of Fenitrothion in Chinese Matrimony Vine and Its Processing Factor by Drying**

H. Jeong, H. Noh, J. Lee, H. Park, J. Kim, M. Jin, Chungbuk National University; S. Hong, National Academy of Agricultural Science; K. Kyung, Chungbuk National University

In this study, the time-course residual pattern of fenitrothion (40% WP) in Chinese matrimony vine was studied and its processing factor by drying was calculated. The test pesticide was sprayed once (T-1, 0.08 g a.i./10 a) or twice (T-2, 0.16 g a.i./10 a) with a 7-day interval. Samples were collected 5 times at 0, 1, 3, 5 and 7 days after last spraying. Drying was done at 60° for 72 h and then the dried samples were blended to make powder. Limits of detection (LODs) of fenitrothion in fresh and dried samples were 0.01 and 0.02 mg/kg, respectively. Recoveries fortified at 10 and 50 times of LODs ranged from 96.1 to 103.2%. Highest residue (HR) in fresh samples harvested at day 0 from T-1 and T-2 were 1.27 and 1.53, while that in fresh samples harvested 7 days after spraying were 0.28 and 0.37 mg/kg, respectively. In case of dried samples, the HR at day 0 from T-1 and T-2 were 1.85 and 2.35, whereas that in the samples harvested 7 days after spraying were 0.28 and 0.37 mg/kg, respectively. These results represented that the pesticide was quickly dissipated in the crop. Processing factors of fenitrothion in Chinese matrimony vine collected from T-1 and T-2 by drying were 1.3-2.3 and 1.5-2.1, respectively, indicating that concentration of the pesticide in the crop was increased by drying.

### WE395

#### **Aerobic Mineralisation in Surface water (OECD 309): Experiences and Interpretation**

W. Völkel, Innovative Environmental Services Ltd; S. Höger, Innovative Environmental Services (IES) Ltd / Environmental Toxicology  
The chemical fate of substances and also the fate of their metabolites is becoming an important part of the environmental risk assessment. One of the required and standardized tests is the aerobic mineralization of substances in surface water. The testing procedure is described in the OECD testing guideline 309, which has now existed for 10 years in its current version. Since every substance is differently to each other, this guideline can only be a framework for the real testing procedure. During the last three years we have performed 30 tests following the OECD testing guideline 309. All test items were <sup>14</sup>C labelled and up to three labels per substance have been tested. The water solubility of the substances varied between the low µg/L and the g/L range, and they were dissolved in water or organic solvents. Volatile

substances were also amongst the tested substances. We tested the behaviour of the substances in different sources of the surface water, which were taken from pond, river and/or lake. As a reference item, radiolabelled benzoic acid was used. The presented results cover a comparison of the degradation rates and of the recovery of this reference item within the thirty tests. In addition to these, the hydrolysis, the degradation and the mineralization of the different test items were also compared. We will show that different types of kinetics are possible. In general mineralisation did not occur often during our studies. Additionally, the effect of suspended solids on the degradation rate was and is still unclear. One important part of the testing, the identification of metabolites, appeared to be very challenging and in some cases more time consuming than expected. In summary, the comparison of the OECD 309 studies, with the different substances with the different characteristics, show that this “standard” test can be simple but can be very complex as well. From a CRO perspective, this leads to different workloads and therefore different prices of the same type of study, which has to be reflected in the study price.

### WE396

#### **Use of public large scale monitoring data for pesticide risk assessment: issues, needs and propositions**

A. Duboisset, A. Boivin, E. FARAMA, ANSES; V. Poulsen, ANSES / French Agency for Food Environmental and Occupational Health Safety  
Water monitoring can be used as the highest tier information for pesticide risk assessment prior to registration (Regulation EC 1007/2009; FOCUS 2009). Large scale public monitoring, routinely undertaken by water agency and/or government bodies, provide however datasets often considered of limited value for risk assessment and related decision making processes. Yet differences noticed between the conclusions drawn from public monitoring datasets and regulatory assessments give rise to debates about pesticide occurrence in water. This presentation explores why datasets from public monitoring are not easy to handle by regulatory authorities for drawing up risk assessment conclusions. It aims at briefly setting out the background that underlies such issue: e.g. divergence between the objectives and rationales of the various stakeholders, and between the different regulations involved; the way how existing large scale water monitoring databases are built and updated at FR level. A short summary of the basic data processing that might be needed to allow such databases to comply with the main objectives of regulatory risk assessment is then provided. Since no guideline on this issue is available at EU level, it emphasizes the need to draw up common EU guidance to assist regulatory authorities and applicants on the way to handle public monitoring data within regulatory procedures for risk assessment. In that view, the place of public routine monitoring (within tier scheme) and their use would need to be discussed. To provide a support for such discussion, two options are considered as example: public monitoring data (e.g. ADES and SoES databases in France) (i) can be provided as background information to the risk manager (e.g. current practice in Anses opinions for the national renewal of PPP in France) or (ii) may trigger additional information in case of positive detections to identify their cause (e.g. German national guidance). Whatever the use of such public monitoring databases, specific approach including reliable statistical methods (e.g. Leterme 2006) and the definition of consistent criteria may be required to ensure consistency of data interpretation. In this regard, proposals from an approach recently developed in France (EIS project: Gauroy *et al.*, 2012) are given.

### WE397

#### **Prospective environmental risk assessments - are we on the right track?**

H. Sundberg, M. Klar, J. Axelman, Swedish Chemicals Agency  
In order to place a plant protection product (PPP) on the market it has to be demonstrated that the PPP doesn’t cause unacceptable effects to non-target organisms. This is demonstrated by prospective risk assessment methods, which are performed by the applicants. The methods have been developed and harmonized within EU. The methods should be valid – they should measure what they claim they measure. And, they should be reliable and ensuring equal treatment for all applicants. The competent authority of the member state where the PPP is to be placed on the market evaluates these risk assessments and makes decisions based on the evaluations. The focus of this analysis is on the validity and reliability of the method. This analysis does not address the degree of protectiveness of the method. Considering the uncertainties not accounted for, and our limited ability to foresee adverse effects in the environment as well as the low reliability (different conclusions from different stakeholders), the appropriateness of the method within a regulatory context is hampered. Standardising the process, reducing negative impact of expert judgment and using fewer but robust predictors can enhance reliability. Nevertheless, the environmental complexity and uncertainties we are unable to consider can still result in a relatively low overall validity even for an improved prospective risk assessment method. Consequently, there is a need for caution when making assumptions about general applicability of data from specific conditions. It is crucial that we understand and acknowledge the limitations with prospective risk assessments, that we adapt our methods accordingly and that the limitations are transparently communicated.

### WE398

#### **Ten years after the Stockholm Convention: What do atmospheric monitoring data tell about its effectiveness in reducing organochlorine pesticides?**

H. Wöhrnschimmel, ETH Zurich; M. Scheringer, ETH Zurich; C. Bogdal, ETH Zurich; K. Hungerbuehler, ETH Zurich / Institute for Chemical and Bioengineering  
In 2014, ten years have passed since the UNEP Stockholm Convention on Persistent Organic Pollutants (POPs) entered into force. The objective of this Convention is to protect human health and the environment from the detrimental effects of POPs by reducing their emissions, where a majority of the substances originally listed for elimination are pesticides. According to the convention, the effectiveness of emission reduction measures is to be evaluated by monitoring POPs in different environmental media. For ambient air, monitoring programs such as EMEP and the UNEP Global Monitoring Plan have collected comprehensive data sets of atmospheric concentrations. Here, we present a time series analysis on organochlorine pesticide concentrations in ambient air. We systematically search for temporal trends and significant structural changes in temporal trends that might result from the provisions of the Stockholm Convention. We find that structural changes do occur in time series of atmospheric concentrations, but they seem to be related not only to effects of the Stockholm Convention, but also to national regulations enforced prior to the implementation of the Stockholm Convention. Also effects of chemical transport and fate, as for instance the revolatilization of POPs from secondary sources, may be the cause of some of the observed structural changes. We conclude that ten years of data are not yet sufficient for detecting any general and statistically significant effects of the Stockholm Convention. Based on these lessons we derive recommendations for the future operation of global monitoring programs, and advocate for a stricter implementation of the precautionary principle, in the current absence of proof for the effectiveness of the Stockholm Convention.

#### WE399

##### **Post-harvest uses of Plant Protection Products: case of study for development of a harmonized environmental risk assessment for non-agricultural uses**

A. Haro, INIA National Institute for Agricultural and Food Research and Technology / Technical Directorate for Evaluation of Plant Varieties and Plant Protection Products; P.V. Gonzalez, Centro de Investigaciones del Medio Ambiente, Dto. Química, Facultad de Ciencias Exactas, UNLP, CONICET; C. Jorquera, INIA National Institute for Agricultural and Food Research and Technology / Technical Directorate for Evaluation of Plant Varieties and Plant Protection Products; E. Prados, INIA; J.L. Alonso-Prados, INIA National Institute for Agricultural and Food Research and Technology / Technical Directorate for Evaluation of Plant Varieties and Plant Protection Products

The zonal evaluation of non-agricultural uses of plant protection products (PPPs) under the framework of Regulation 1107/2009 is not harmonised. The first step in the environmental risk assessment is to consider the likelihood of exposure. Consequently, there is a need of defining emission pathway diagram in relation to the type of application in order to rapidly detect the concerned environmental compartments. In this work we present a methodology to cope with this type of uses considering post-harvest treatment as a case of study. Under Regulation 1107/2009, post-harvest treatment is considered as interzonal evaluation and currently there is no harmonised risk assessment scheme at zonal level for this kind of use. Post-harvest processes are integrated in the food production system involving an outstanding economic and health value. These processes include the use of plant protection products (PPP) to prevent pests and diseases during the storage and commercialization of commodities. PPP intended to be used in post-harvest treatments have been considered as indoors treatment with a negligible environmental exposure. However, post-harvest technology is an industrial process with a high consumption of water which implies waste water emission that may lead to exposure to different environmental receptors. In this work we propose an emission scenario to quantify the exposure to the different concerned environmental compartments for post-harvest uses based on the work and knowledge from risk assessment approaches developed for biocides and industrial chemicals, as an attempt for harmonization of environmental risk assessment approaches at EU level for this kind of uses.

#### WE400

##### **EFSA opinion on good modelling practice and stakeholders' perceptions of ecological models: expectations vs. reality**

M. Meli, Rifcon GmbH; A. Hunka, University of Twente / Faculty of Behavioural Sciences; A. Palmqvist, Roskilde University / Department of Environmental Social and Spatial Change; J. Ludwigs, Rifcon GmbH; V.E. Forbes, University of Nebraska Lincoln / School of Biological Sciences

In March 2014 EFSA published a scientific opinion on good modelling practice (GMP) in the context of mechanistic effect models (MEMs) for risk assessment of plant protection products. In this opinion, the panel on plant protection products and their residues identifies a number of critical steps in setting models within risk assessment, and suggests criteria for model evaluation by regulatory authorities. Availability and quality of the scientific data underlying the model, plausibility of the model's general behaviour, documentation of the development process, correspondence with available independent observations, and fit of the model for the proposed regulatory purpose are stressed as the most important points that a risk assessor should evaluate. In 2013 we published an analysis of stakeholders' perspectives on ecological modelling in environmental risk assessment of pesticides. In the light of the conclusions we drew after interviewing 43 stakeholders from academia, industry and regulatory authorities, we analysed the

EFSA opinion in order to assess to which extent the needs and expectations expressed by our participants are addressed in the opinion. This analysis shows that several points of concern expressed by our participants are addressed in the opinion. For instance, the thorough discussion on data support and the necessity of lab/field work, addresses the worries of stakeholders who believed that modelling could entirely replace empirical data. Also, the GMP opinion's pragmatic approach to species selection addresses one of the concerns that many stakeholders had. However, the scientific opinion appears to be inconsistent in the area of "validation", one of the most controversial and confusing aspects emerging from our interviews, and with regard to real vs. generic species to be modelled. Uncertainty factors also appear to be a step backwards, compared to the expectations of several interviewees, who felt strongly against cut-off criteria and similar instruments. In conclusion, while a number of the needs and concerns expressed by stakeholders to be hindering the process of introducing MEMs into risk assessment are addressed in the GMP opinion, several questions remain open. Among other topics we think it is necessary to further discuss 1) how to deal with proprietary models, 2) how operational the recommendations offered in the opinion are, and 3) how to optimize the work for both modellers and risk assessors.

#### WE401

##### **Pesticide resistance risk indication: A prospective approach based on pesticide usage data**

M. Plath, L. de Baan, O. Daniel, Agroscope / Institute for Plant Production Sciences IPS

The spread of pesticide resistant fungi, weeds and insects is the result of synergistic effects between natural selection and the selective pressure of pesticides. Pesticides primarily kill sensitive target organisms while promoting the survival and reproduction of the less susceptible ones. Thus, the usage of pesticides, particularly the application of the same active ingredient or of active ingredients with the same mode of action over the long-term, may foster the resistance of the target organisms. Information on the farmers' strategies of pesticide usage may therefore provide an important measure to assess the pesticide resistance risk in individual crops. In Switzerland, an agri-environmental monitoring system was launched in 2009. Within this monitoring, pesticide usage surveys are conducted annually. About 300 farmers voluntarily report their pesticide usage, including applied product, amount, time and crop for each pesticide application. We hypothesized that these usage data may be used to deduce the risk of potential pesticide resistance in specific crops by evaluating the diversity of active ingredients and related modes of action used. A set of diversity indices were tested for their suitability to serve as pesticide resistance risk indicator. Low diversity was assumed to be indicative for a high pesticide resistance risk. The applied active ingredients were grouped according to their mode of action, as defined by the Resistance Action Committee for fungicides (FRAC), insecticides (IRAC) and herbicides (HRAC). First results revealed significant differences across crops regarding the diversity of pesticide used, suggesting that certain agricultural systems may undergo an increased risk of pest resistance. A yearly update of such an indicator could provide information on the long-term development of potential risks of pesticide resistance and could be assessed alongside with the long-term development of the ecotoxicological risk of the applied active ingredients. However, further tests are required to validate the use of diversity indices as possible pesticide resistance risk indication.

#### WE402

##### **Why time matters: A stock-pollution approach to regulating PBT/vPvB chemicals**

S. Gabbert, Wageningen University / Social Sciences; L. Hilber, Agroscope ART  
A core aim of the chemicals' legislation in Europe is that hazardous chemicals are adequately controlled. For chemicals for which an adequate control of the risks is considered not possible decision-making on the use or non-use is increasingly based on a socio-economic analysis (SEA). A SEA is expected to allow for a more balanced decision, where the gains from keeping a chemical in use are opposed to expected damage costs for society. Here we argue that for chemicals which are, in addition to their toxicity, persistent and/or bioaccumulative (PBT/vPvB chemicals), the weighing of benefits against costs must account for stock pollution effects, causing environmental concentrations in a compartment to increase over time. We explore how stock pollution effects can be incorporated into a SEA. For this purpose we first develop a dynamic model for assessing stock effects in an environmental compartment. The model illustrates that stock dynamics, i.e. the increase of environmental concentrations over time, depend on the interplay of the initial concentration, the release rate, and a chemicals' degradation half-life. Including the model into a cost-benefit analysis approach allows identifying the decision rules for the use or non-use of a PBT/vPvB chemical. We demonstrate that ignoring stock pollution effects in a SEA may lead to erroneous decisions on the use of PBT/vPvB chemicals because long-term impacts are not adequately captured. Furthermore, whether or not a PBT/vPvB chemical should be authorised, and for what period, crucially depends on the shape of the damage function. Using a historic case of DDT soil contamination as an illustrative example, we discuss implications for risk management decision-making of PBT/vPvB chemicals in different regulatory frameworks. Our analysis emphasises the urgent need for developing thorough and detailed guidance for both companies and decision-makers in regulatory agencies on how to assess stock pollution effects of these chemicals.

#### WE403

##### Aquatic Risk Assessment for Triazole Fungicides: The Impact of Epoxiconazole and Tebuconazole on Aquatic Fungi

L. Wiesner, Goethe University Frankfurt / Department Aquatic Ecotoxicology; L. Werner, Swiss Centre for Applied Ecotoxicology / Department of Anatomy Physiology and Cell Biology; M. Junghans, Swiss Centre for Applied Ecotoxicology EAWAG - EPF / Ecotox Centre

The risk of fungicides to aquatic fungi has been disregarded in aquatic risk assessment so far. Besides classically tested aquatic organisms like fish, crustaceans, algae and higher plants, aquatic fungi like hyphomycetes or yeasts play an important role in the food web dynamics of aquatic ecosystems. Therefore this study aims at establishing a reliable and easy to handle testing method to assess the possible influence of fungicides like epoxiconazole and tebuconazole on aquatic fungi. Two tests were set up: (i) a growth test with the aquatic yeast *Cryptococcus laurentii* (Basidiomycota) and (ii) a growth test with the hyphomycete *Tetrachaetum elegans* (Ascomycota). In the 96-well plate bioassay with *C. laurentii* an EC50 value of 0.0458 mg/L and an EC10 value of 0.0073 mg/L was derived for epoxiconazole. For tebuconazole the EC50 and EC10 were 0.131 mg/L and 0.126 mg/L, respectively. This is in accordance with literature data for the aquatic yeast *Cryptococcus flavescens*. A species sensitivity distribution (SSD) with acute toxicity data from aquatic vertebrates, invertebrates, algae and higher plants shows *C. laurentii*, besides *Lemna gibba* (0.144 mg/L) as the most sensitive organism for tebuconazole. For epoxiconazole, the growth test with the aquatic hyphomycete *T. elegans* resulted in an EC50 of 0.0329 mg/L, which is similar to the yeast EC50 of 0.0458 mg/L. Due to time constraints the yeast test could only be carried out twice, therefore the results need to be verified, and additional influencing factors should be investigated; e.g. smaller mycelia starting size led to an increase of test sensitivity. When cellulose filters were used as organic substrate a decrease in filter-colonisation was observed in the presence of epoxiconazole. Both tested fungal species are among the most sensitive aquatic organisms for triazole fungicides. Hence, the consideration of aquatic fungi in triazole fungicide risk assessments is of great importance. With regard to the growth endpoint, the yeast bioassay is the more promising test, because it has a shorter test duration and allows for the testing of a higher number of replicates in the same run. Since sporulation might be a more sensitive parameter than growth, a hyphomycete sporulation bioassay needs to be developed for assessing the chronic toxicity of fungicides on aquatic fungi – unfortunately we were not able to induce sporulation in the hyphomycete strain.

## Reduction strategies of micropollutants from large and small-scale sewage water facilities (P)

#### WE404

##### Natural zeolite as an alternative sorbent for the toxic dye Rhodamine 6G removal

Z.L. Yaneva, Trakia University, Faculty of Veterinary Medicine / Chemistry; N. Georgieva, Trakia University / Chemistry

**Introduction** Rhodamine 6G (R6G, Basic red 1) is a cationic fluorescent azo dye applied widely in textile industry, as a genetic marker/cell staining in biochemistry. Its carcinogenicity, reproductive and developmental toxicity, neurotoxicity and chronic toxicity to humans and animals was experimentally proven. Thus, the removal of R6G from industrial wastewaters is important in terms of protection of public health, environment and aquatic life. The aim of the present study was to present an alternative methodology for the removal of R6G from aqueous solutions by using natural zeolite. **Materials** R6G ( $C_{28}H_{31}N_2O_3Cl$ ) was obtained from Sigma-Aldrich. Dye concentrations were determined spectrophotometrically at 524 nm. The standard curve was linear over the range of the tested concentrations ( $R^2$  0.9986). The natural zeolite used in the present study was supplied from deposits in Bulgaria. Zeolites surface chemistry and morphology were characterized by Boehm titration, pH point of zero charge ( $pH_{PZC}$ ), FTIR and digital microscopy analyses. **Results** The sorption characteristics of R6G on the natural sorbent were investigated in a batch mode in the concentration range 5.0–35.0 mg/L, with sorbent mass 0.5 g and equilibrium time 24 h. The UV/VIS spectra of R6G within the pH range 2.5–10.5 did not display shifting of the absorption peaks. The intensity of the absorption maximum at pH 5.8 was the highest. The  $pH_{PZC}$  of natural zeolite was 7.35. The digital microscope images of the fresh and dye-loaded zeolite displayed samples heterogeneity and irregular distribution of dye macromolecules on the solid particles surface. The positions of the peaks in the FTIR spectra of the fresh and R6G-loaded zeolites were approximately similar but the band intensities of the dye-loaded sorbent decreased. The maximum equilibrium zeolite capacity towards R6G was 2.8 mg/g. Experimental data showed a good fit with the multilayer model ( $R^2$  0.9953). It allowed the calculation of both the monolayer sorption capacity (1.625 mg/g) and the equilibrium constants for the first layer ( $K_1$  49.218) and subsequent ( $K_2$  0.0688) adsorption. The monolayer capacity of zeolite according to the Langmuir model was 2.79 mg/g. The highest established extend of the dye uptake was 83 %. In conclusion, due to its low cost, availability, and satisfactory dye uptake capacity natural zeolite can be successfully applied for R6G removal from aqueous solutions. **Keywords:** Rhodamine 6G, natural zeolite, sorption

#### WE405

##### Isoniazid removal from water by adsorption on acid-modified zeolite

N. Georgieva, Trakia University / Chemistry; Z.L. Yaneva, Trakia University, Faculty of Veterinary Medicine / Chemistry; S. Stanilova, D. Petrova, Trakia University; M. Staleva, University Prof. Assen Zlatarov

**Introduction** Isoniazid (INH, Rimifon), a first-line medication used in the treatment of infections caused by *Mycobacterium tuberculosis*, could be attributed to the group of „emerging” pollutants. Released into the environment, these pharmaceutical biologically active substances are active even in small amounts as they pollute natural waters and destroy or inhibit the activity of certain microorganisms important for the ecosystems. The aim of the present study was to investigate the physicochemical, morphological characteristics and adsorption capacity of acid-modified zeolite as cost-effective alternative adsorbent for isoniazid removal from water. **Methods** INH concentrations were determined by an adapted UV/VIS method at 262 nm. The standard curve was linear over the range of the tested concentrations ( $R^2$  0.9996). The natural zeolite used in the present study was supplied from deposits in Bulgaria. It was modified with 4M HCl. Zeolite surface chemistry and morphology were characterized by determination of pH of zero charge, FTIR and digital microscopy analyses. **Results** The analysis of the experimental results established that the highest extend of INH uptake during the kinetics study was 95.5 %, achieved at initial drug concentration 100 mg/L, mass of zeolite 1 g and contact time 320 min at 22°C. The pseudo-second order kinetic model displayed an extremely high degree of correlation ( $R^2$  0.9996). Thus, the rate-limiting step during INH adsorption on zeolite might be chemisorption involving valency forces through exchange of electrons between the drug molecule and zeolite. The highest equilibrium zeolite capacity towards INH was 7.17 mg/g. The Sips model best represented the experimental equilibrium data ( $R_s^2$  0.980) of the drug sorption on zeolite. The integrative analysis of surface chemistry/sorption studies showed that the probable sorbate-sorbent interactions include van der Waals forces, H-bonds and chemical interactions between INH functional groups and zeolite silanol groups, as well as parallel intraparticle diffusion of drug molecules in the mesopores of the mineral particles. In conclusion the unique properties of zeolite and the established high extend of INH sorption proved the possibility of its successful application for the removal of the drug from aqueous phase. **Keywords:** isoniazid, emerging pollutants, zeolite, sorption **Acknowledgements:** The study was supported financially by Project NoSP-40/UP, Trakia University, Stara Zagora, Bulgaria.

#### WE406

##### Pilot scale ozonation of problematic wastewater contaminants: clarithromycin, 1h-benzotriazole and carbamazepine - Consequences regarding ecotoxicity and transformation products

M. Posselt, Department of Applied Environmental Science ITM; M. Radke, Institute for Hygiene and Environment / Environmental Laboratory; M. Breitholtz, Inst för tillämpad miljövetenskap / Department of Applied Environmental Science ITM; P. Schwartz, Federal Environment Agency Germany; T. Meinelt, Leibniz Institute of Freshwater Ecology and Inland Fisheries

Ozonation has been proposed as a technology for quaternary wastewater treatment to improve the removal of anthropogenic trace contaminants. However, wastewater ozonation under economically feasible conditions does not necessarily result in complete oxidation of organic compounds but can instead lead to the formation of largely unknown transformation products (TPs). Results from several studies suggest that certain TPs might have a higher ecotoxicological potential than the original substances. There is still a lack of data on arising TPs and on the consequences for aquatic ecosystems. What is missing in particular are data from combined approaches comprising both advanced analytical as well as ecotoxicological test methods. In this study we investigated the effects of the TP mixtures from three organic micropollutants [clarithromycin (CL), 1h-benzotriazole (BZ), carbamazepine (CBZ)] on different test organisms according to OECD TGs: 201 (*D. subspicatus*), 221 (*L. minor*) and 236 (*D. rerio*). In parallel, we searched for TPs in ozonated samples using HPLC/Q-TOF. Removal efficiencies and test concentrations were measured by UHPLC MS/MS.  $O_3$  treatment was carried out at a pilot plant integrated into a municipal sewage treatment plant (STP) at Stockholm, Sweden. Either effluent water (EW) from the STP or tap water (TW) was spiked with elevated concentrations of the chemicals, ozonated, aerated and finally sand filtered. We applied retention times (20 min) and  $O_3$  doses (0.6 g  $O_3$ /g TOC) that were previously described as economically feasible for large-scale application in STPs. Ozonation of EW controls and TW controls revealed no adverse effects in ecotox tests. CL was removed to >99% from both EW and TW. CBZ was completely removed from EW. BZ revealed as more recalcitrant with removal rates between 0% and 59%. The obtained TP mixtures of BZ and CL were either less toxic than the parent substances or non-toxic in ecotox tests. Sandfiltration did not entirely remove TPs and the overall removal of parent compounds was not significantly improved. CL-N-oxide was identified as the main TP of CL. In contrast to the parent substance, its toxicity towards algae was negligible. Our data suggest that EW ozonation is an effective tool to address the problem of critical CL concentrations in surface waters reaching the tentative recommended environmental quality standard ( $QS_{FW, eco}$ ) of 0.130 µg/L, as well as to improve the removal of CBZ and, to a minor degree, BZ.

#### WE407

#### **Benefit of wastewater treatment plant upgrading with activated-carbon filters for connected freshwater ecosystems**

P. Thellmann, H. Köhler, Tübingen University / Animal Physiological Ecology; K. Wurm, GÖL Water Ecology Laboratory Starzach; R. Trieborsk, University of Tübingen / Animal Physiological Ecology

Advantages of wastewater treatment plant (WWTP) upgrading with additional cleaning stages as, e.g., ozonation or powdered activated-carbon (PAC) filtration, are a late-breaking topic in sanitary environmental engineering, and the efficiency of the available technologies for the reduction of micropollutants and pathogens is a matter of intense scientific discussion. Whether or not this reduction of chemicals does result in an improvement of ecosystem health, however, is far from being understood. The two WWTPs Ebingen (located at the Schmiecha River) and Lautlingen (located at the Eyach River), both in Southern Germany, have been upgraded with powdered activated-carbon filters more than 20 years ago, at that time aiming at reducing stains released by local textile industry from the effluents. Prior to the upgrade, the rivers Schmiecha and Eyach were highly polluted ("stained in all colours") and biota were hard to find. After the upgrade of the two WWTPs, the quality of the receiving water courses has continuously improved. Nowadays, pollution by stains has decreased dramatically due to close-down of textile industry. As a result, the reduction of "modern" micropollutants by active-carbon filtration has more and more moved into the focus of interest. In order to show the long-term efficiency of the WWTP upgrading for the connected rivers Schmiecha and Eyach in this context, we investigated ecosystem health upstream and downstream of the two WWTPs by means of biomarker analyses in fish (including investigations of tissue integrity, stress protein levels, and micronuclei in erythrocytes), biotests for developmental toxicity, assessment of the fish population structure, and by calculation of ecological indices. The results indicate a healthy status of fish and invertebrates both upstream and downstream of the two WWTPs, and reflect the high efficiency of the powdered activated carbon stages for sewage effluent cleaning and, thus, for ecosystem integrity of the rivers Schmiecha and Eyach.

#### **WE408**

##### **Thermally Activated Persulfate Removal of Cyclohexanecarboxylic Acids and Radical Mechanisms**

X. Xu, Universidad Autónoma de Madrid; J.E. Silveira, Ingeniería Química; G. Pliego, J. Zazo, J. Casas, Universidad Autónoma de Madrid; J. Rodríguez, Autonomous University of Madrid

Nowadays, increasing attention has been paid on the environmental impact of Naphthenic acids (NAs) from oil sands process-affected water (OSPW). NAs are series of alicyclic carboxylic acids with extreme toxicity. In the current work, cyclohexanecarboxylic acid was chosen as the model pollutant to be treated by thermally activated persulfate oxidation at pH = 8, with the aim of complete removal of CHA and learning on the radical mechanisms involved. An initial CHA concentration of 50 mg/L was used. The amount of persulfate was varied from 0 to 100% of the stoichiometric dose toward CHA. The effect of working temperature was considered. Radical mechanisms were investigated by adding the scavengers (tert-butyl and ethanol) to the systems, and the effect of chloride (14.3 mM) ions were investigated. The results indicated that complete mineralization of CHA could be achieved by 2.8 mM persulfate under 80 °C. The rate of TOC removal was well described by a simple pseudo-first order rate equation. Sulfate and hydroxyl radicals were believed to be the reactive species for the degradation of NAs, and the former were verified to be the dominant radicals. The evolution of hydroxyl radicals was studied by adding quenching agent at different reaction times. Chloride was proved to be of little impact toward the removal of CHA.

#### **WE409**

##### **Ecotoxicological assessment of domestic wastewater treated by membrane technology**

P. Palma, Instituto Politécnico de Beja / Department of Technologies and Applied Sciences; S. Fialho, Polytechnic Institute of Beja; C. Santos, CEBAL; G. Palma, C. Cavaco, R. Gomes, EMAS; L. Neves, CEBAL

With the increment of world's population and the consequent demand for water supply, the sustainable development and the conservation of water resource will require the reuse, recycling and the improved quality of wastewater discharges. In this context, the membrane filtration processes, may be considered an efficient and economic technology, which could be integrated in wastewater treatment plants (WWTPs) for the increment of the physical, chemical and ecotoxicological properties of the wastewater. The aim of the present study was to characterize and evaluate the efficiency of nanofiltration (NF90, NF270) and reverse osmosis (SW30) membranes, in improving the quality of the effluent from the WWTP Mine of Juliana (Portugal), in order to reduce the impacts in the Roxo reservoir. The efficiency of the proposed treatment processes were assessed by: (i) chemical parameters such as, total nitrogen, total phosphorus, carbon organic demand (COD), biochemical oxygen demand (BOD<sub>5</sub>); and (ii) ecotoxicological effects through the use of representative species of different taxonomic and functional groups (*Vibrio fischeri*, *Thamnocephalus platyurus*, *Daphnia magna*, *Pseudokirchneriella subcapitata*). The results indicated that the three membranes have high removal percentages for the most parameters studied. All parameters concentrations are below the legal limits, according to the Decree-Law N.º 152/97 of 19 June, except the total nitrogen, with the NF270 membrane. With respect to the ecotoxicological effects, in general, the use of membranes removed the toxicity

detected in the initial samples (classified as Class 2 of UT). The SW30 membrane showed a greater toxicological efficiency removal comparing with the nanofiltration membranes. Further, among the nanofiltration membranes used, the NF90 promoted a greater decrease in the toxicity of the samples. Thus, treatment with the membranes NF90 and SW30 allowed obtaining an effluent with high quality and low ecotoxicological potential, without endangering the environmental balance in the water resource.

##### **Assessment of the hydraulic performance of activated sludge plants and its influence over estrogen degradation**

T. Coello García, T.P. Curtis, Newcastle University / Environmental Engineering; P. Meynet, Newcastle University / CEGS; W. Mroziak, Newcastle University / School of Civil Engineering Geoscience; R. Davenport, Newcastle University / School of Civil Engineering and Geosciences

Natural and synthetic estrogens have been detected worldwide in wastewater treatment plants effluents. They have been reported to be responsible for endocrine disruption and, although currently unregulated, they are on an EU monitoring list for prospective legislation, with a proposed environmental quality standard (EQS) for E2 and EE2 of 0.4 and 0.035 ng/L respectively. This increases pressure on the water industry to implement highly expensive tertiary treatment technologies in their wastewater treatment plants (WWTP) to comply with these standards. There is evidence that activated sludge (AS) processes can achieve the requisite removal of estrogens, but its optimisation is poorly understood. Operational parameters such as the solids retention time (SRT) and the hydraulic retention time (HRT) have been suggested to influence estrogen degradation, but this is difficult to assess on full-scale plants due to the variations in flow and insufficient control. Furthermore, the hydraulic performance of the aeration tank (i.e. completely stirred tank reactor (CSTR) or plug flow) has not always been taken into account. A series of tracer studies were performed in several aeration tanks in conventional AS WWTPs to gain information on their real HRT and hydraulic regime. The results of these studies were fitted to the dispersion and tanks in series models, and the Aquasim software was used to account for recirculation in the systems. Typical influent concentrations and degradation constants from the literature were used to predict the removal of estrogens in those reactors based on the observed HRT and hydraulic regime. Thus, for influent concentrations between 2.4 and 150 ng/L for E2 and 0.5 and 70 ng/L for EE2, and degradation constants between 0.174 and 5.75 h<sup>-1</sup> for E2 and 0.006 and 0.1 h<sup>-1</sup> for EE2, in the worst case scenario the difference in the percentage of removal among a CSTR and a plug-flow accounts for as much as a 16%, which, at low influent concentrations, was enough to ensure an effluent concentration below the EQS. The results also showed that the observed HRT differs considerably from the theoretical HRT in the studied reactors, which appreciably varies the predictions for removal rates, thus emphasizing the importance of its accurate determination. This assessment points out that some existing WWTPs would not necessarily need major investments in tertiary treatment, but an improvement in their hydraulic performance, to meet the required standards.

#### **WE411**

##### **Non-target analysis and prioritization of compounds emitted from on-site sewage treatment facilities**

K.M. Blum, Umea University / Department of Chemistry; P.L. Andersson, Umea University / Chemistry Department; B. Björnlén, G. Renman, KTH Royal Institute of Technology; P. Haglund, Department of Chemistry

Many households in Sweden are not connected to any central sewage treatment plant and therefore use on-site sewage treatment facilities (OSSFs). The emissions of micropollutants to surface and ground waters from those facilities are largely unknown, which calls for a thorough effluent and removal efficiency characterization. Influent and effluent samples were collected from Swedish on-site sewage treatment facilities (OSSFs), including: soil beds, miniaturized sewage treatment plants (STPs) and source-separated systems. In addition a set of samples were taken from medium sized municipal STPs (without industrial input) and one large municipal STP. OSSF influents or effluents from facilities with similar treatment technique were pooled after filtration. Pooled filter and water samples were extracted using Soxhlet extraction with toluene and using liquid-liquid extraction with dichloromethane, respectively. The corresponding water and filter extracts were combined and analyzed with comprehensive gas chromatography time-of-flight mass spectrometry. Full-scan spectra were compared to the NIST mass spectral library for preliminary identification. Manual investigation of peaks with >65 % spectra similarity assured the spectral quality of the library hits. Features were excluded if they had elevated blank levels, originated from column or septa bleed or had a low detection frequency. Environmental fate parameters for the tentatively identified compounds were estimated with the EPISUITE *in silico* tool by the US Environmental Protection Agency and use information was extracted from EU and national databases. Priority ranking according to persistence, bioaccumulation, toxicity, concentration levels and removal efficiencies resulted in a final list of environmentally relevant chemicals discharged from OSSFs. Amongst the priority compounds were food additives, fragrances, detergent ingredients, cosmetic additives, plastic additives and biocides. These will be targeted in a recently started project entitled RedMic aiming at improving the OSSF treatment technologies and reducing diffuse emissions from OSSFs.

#### WE412

##### **Active biomonitoring to evaluate efficiency and potential impacts on coastal area from submarine discharge point of an industrial integrated waste water treatment plant**

f. Perin, Thetis Ltd; I. Corsi, University of Siena / Physical Earth and Environmental Sciences; E. Andreoli, M. Bergamin, THETIS SpA; M. Vannuccini, University of Siena / Physical earth and environmental science; e. bergami, University of Siena / Physical Earth and Environmental Sciences; e. bocci, University of Siena; C. Nasci, Thetis Ltd / European Union and RD  
In 2014, in the framework of an integrated monitoring program, mussels (*Mytilus galloprovincialis*) originating from the same population grown in a mussel farm, were transplanted for 30 days near and far from the treated water submarine input and at a reference site. Summer and Winter exposure experiments were performed and samples analyzed for organic micro-pollutant and metal contents and biomarkers in different organs. Bioaccumulation of IPA, PCB, chlorinated pesticides and metals were carried out in whole soft tissue of mussels. As for biomarkers, stress on stress and Condition Index were determined as general index of animal status. Catalase, Malondialdehyde and Total Metallothionein content were measured in digestive glands while lysosomal membrane Stability (NNRT) and micronucleus in haemocytes. The chemical and biological results will be elaborated in order to provide an evaluation of health condition of animals related to the contamination level and indirectly of the surrounding environment. The data, responding to the legislation requests related to EIA, will contribute to define monitoring protocol to be used to evaluate the treatment efficiency and ecosafety of similar industrial integrated waste water treatment plants.

#### WE413

##### **Optimization of parameters of small wastewater treatment facilities, the OPTITREAT project**

H. Ejhed, IVL Swedish Environmental Research Institute; J. Magner, IVL Swedish Environmental Research Institute Ltd; E. Dorgeloh, PIA RWTH Aachen University; G. Plaza, Institute for Ecology of Industrial areas

Onsite wastewater treatment is of great concern due to the load of phosphorous and nitrogen contributing to the eutrophication of the recipients. The load of household related hazardous substances as pharmaceuticals, personal care products and antibiotic resistant genes are of further concern, since even very low concentrations can cause effects on the ecosystems and contaminate drinking water resources. The WHO has recently identified the increased spread of antibiotic resistant genes as one of the largest threats to mankind in the future. However, onsite wastewater treatment optimized to mitigate wastewater pollution, could offer cost-efficient solutions. In remote areas and areas lacking infrastructure, onsite wastewater treatment is the only alternative. This work presents results from a sand-filter bed spiked with a pharmaceutical cocktail of fifteen substances, showing more than 60% reduction of most substances, but 30% reduction of the calcitrant substance carbamazepine. Thus, the results implicate that onsite wastewater treatment could have better or equally good reduction efficiencies as many conventional active sludge WWTP's. However variations in the reduction efficiencies in this study as well as in literature reveal the need for in-depth studies and optimization of the parameters driving the reduction processes. This BONUS financed project continues to focus on the physico-chemical and technical aspects of optimizing the processes driving the onsite wastewater treatment systems. Wastewater treatment is performed by combinations of mechanical, chemical and biological treatment. Simulation tests on daily flow pattern, overloading and underloading are performed using three type techniques allowed for testing at the European test center for certified small wastewater of treatment facilities in Aachen, Germany. The tests aim at a holistic assessment of reduction efficiencies of: nutrients, pathogens, pharmaceuticals, personal care products and antibiotic resistant genes. Parameters that are monitored and varied are primarily: pH, redox, temperature and residence time. Results will lead to a benchmark state of the art of the parameters controlling the reduction efficiencies in the onsite wastewater facilities, allowing for optimization to meet the demands of reducing risk of contaminating recipients and drinking water.

#### WE414

##### **Strategies to Reduce Diffuse Emissions of Micropollutants from On-Site Sewage Treatment Facilities**

P.L. Andersson, Umea University / Chemistry Department; E. Kärrman, KTH Royal Institute of Technology / Land and Water Resources Engineering  
Nearly 700 000 private households in Sweden are not connected to any central wastewater treatment plants and emissions of organic micropollutants (MPs) from on-site sewage treatment facilities (OSSFs) are in large unknown. The recently initiated research project RedMic is devoted to develop strategies and techniques to reduce emissions of MPs from OSSFs. The overall aims are to 1) identify and quantify emissions of MPs from OSSFs, 2) develop and evaluate novel innovative OSSFs techniques, 3) identify major sources of MPs emitted from private households, and 4) suggest an efficient strategy for reduction of diffuse emissions from private households. In this presentation the initial findings will be presented on the development of a multi-criteria analysis as a basis for a decision support strategy for management of diffuse emissions from OSSFs. A step-wise multi-criteria analysis approach will be undertaken including 1) definition of

system boundaries, 2) selection of criteria covering ecological, economical and social dimensions, 3) selection of system alternatives i.e. possible options for reducing MPs including source control, changes in human behaviour and technical improvements, 4) prioritisation and weighting of the criteria in a workshop with a stakeholder group, and 5) comparison of the different options using the criteria from step 2. The final model comparison will be done using substance flow-, cost- and energy analysis and also qualitative assessment. Here initial factors will be discussed including aspects of technical solutions, e.g. soil beds and small scale sewage water treatment techniques with various additional reduction steps including ozone treatment and charcoal filtration, applicability, life cycle costs, operation, maintenance, emission reductions, and regulatory aspects.

#### WE415

##### **Development of Microbial Electrogenic Technologies for removal of emerging pollutants from wastewater**

K. Boltes, University of Alcalá / Chemical Engineering; A. Pun, University of Alcalá / Chemical Engineering; P. LETÓN, Univ. ALCALÁ; A. Esteve, University of Alcalá / Chemical Engineering; J. Salas, J.R. Pidre, Fundación Centro de Nuevas Tecnologías del Agua (CENTA); L. Nozal, IMDEA Water  
Emerging pollutant are not completely removed in current sewage treatments so they become recalcitrant. The problem is even more relevant if we take into account that an important amount of wastewater associated to small and rural populations (< 2000 eq-hab) is not treated at all. This population (around 3-4 million habitants in Spain) still do not have access to any kind of wastewater treatment so emergent pollutants as well as pathogens are dairy released into the environment. That small populations show a range of technical and economic features that makes low-energy and simple operation treatments the most appropriated for treating their wastewater. Wastewater technology based on biological treatments requires a suitable electron acceptor for consuming the electrons generated in the microbial metabolism of organic matter. Microbial electrogenesis consists in using of conductive material for accepting all those electrons from bacteria so an electric current could be harvested. By using such a conductive material bacteria are not limited in the availability of electron acceptor so its biodegradation oxidative rates become enhanced. On top of that, the presence of conductive material allows novel syntrophic mechanisms based on Direct Interspecies Electron Transfer (DIET) so microorganisms expand their profile of substrates. In this work, we evaluate the role of microbial electrogenesis in the biodegradation of emerging pollutants. Our strategy is not just limited to carry out assay at lab scale. Since 2010, the authors have been working together for coupling microbial electrogenesis with extensive technologies as artificial wetlands. Our research team has developed a full scale artificial electrogenic wetland which is dairy fed with urban wastewater and placed at CENTA facilities (Carrión de los Céspedes, Seville). We evaluated the removal capability of our system in field and at lab scale, measuring a set of 15 emerging pollutants (Atenolol, Paraxanthine, 4-AA, 4-DAA, Codeine, Caffeine, 4-AAA, 4-FAA, Sulfamethoxazole, Citalopram HBr, Carbamazepine, Ketoprofen and Naproxen) by GC-MS analysis coupled by a set of toxicity test using different aquatic organisms (algae, plants). Our results show that electrogenic wetlands are an interesting tool to assay the effect on conductive material on emerging pollutants biodegradation under real conditions

<sup>3</sup>Universidade Nacional de Mar del Plata <sup>4</sup>University of Toronto

E-mail: patcosta0@gmail.com gfillmann@gmail.com  
Keywords: passive atmospheric samplers, Brazil, POPs, XAD2-based PAS XAD-2 passive air samplers were deployed between the years 2010 and 2013 installed at 31 sites in Brazil covering areas of different backgrounds (industrial, rural, urban and low-impact areas). As part of the Latin American Atmospheric Passive Sampling Network (LAPAN), this work was initiated to address the lack of knowledge on the fate of legacy and current-use pesticides in South America, particularly in Brazil. Regional and global sources and spatial and temporal distribution of POPs, but also PAHs, CUPs and PPCPs, are being assessed. This study is allowing Brazil to comply with some aspects of the Stockholm Convention demands concerning the identification of main sources, provision of monitoring comparable data on POPs contamination to allow an assessment of its effectiveness. Making it possible to increase the present spatial and temporal resolution run by GAPS (Global Atmospheric Passive Sampling Network) and requested by the Guidance on the

Global Monitoring Plan (GMP) for POPs. Of the pesticides measured, concentrations in air were dominated by PCBs, DDTs, endosulfan (and its metabolites in low concentrations) and the current-use pesticides (CUPs): Dichlofluanid, chlorothalonil, atrazine and trifluralin. Other pesticides that were regularly detected included  $\alpha$ - and  $\gamma$  hexachlorocyclohexanes (HCHs) and dieldrin. PAHs, PBDEs and emerging contaminants (bisphenol-A, iprodione, Irgarol, terbutconasol and methylparaben) were present in many samples. These data are consistent with previous studies in regions in South America and contributed to the increase significant the spatial and temporal resolution in a sustainable manner to cope with long-term studies. Some of Brazil results (mainly background sites) were incorporated in the second Global Monitoring Report, which will be presented for the 2014 Conference of the Parties of the Stockholm Convention on Persistent Organic Pollutants.

#### WE417

##### **Air quality in stations and trains in the Barcelona subway system**

**V.I. Martins**, Institute of Environmental Assessment and Water Research (IDAEA-CSIC); T. Moreno, Geosciences; M. Minguillón, X. Querol, Institute of Environmental Assessment and Water Research IDAEA-CSIC  
People living in metropolitan areas usually spend a considerable amount of their daily time commuting. In today's society, the subway is a well-developed and highly promoted transportation mode because of its comfort, high speed, environmental friendliness, and large transport capacity. However, prior studies in subway systems of several cities worldwide indicated that particulate matter (PM) concentrations are generally higher in these environments than those measured in ambient air. The passengers are exposed to indoor air potentially polluted by various sources, including the abrasion of rail tracks, wheels, catenary and brake pads produced by the motion of the trains, and the movement of passengers which promotes the mixing and suspension of PM. An extensive measurement campaign was performed in the Barcelona subway system in order to characterise PM measuring its concentration and investigating its variability, both inside trains and on platforms, in two different seasonal periods (warmer and colder), to better understand the main factors controlling it, and therefore the way to improve air quality. The subway system comprises eight subway lines, at different depths, with different tunnel dimensions, stations designs and train frequencies. Four subway stations were selected for daily measurements and supplementary samplings were also performed in a total of 20 additional stations. Chemical composition of a total of 236 daily PM<sub>2.5</sub> filters sampled in the 4 different platforms was also investigated. Measurements inside the trains were carried out in six subway lines. PM concentrations varied widely among underground stations, according to different ventilation and air conditioning systems, characteristics of each station and variations in the train frequency. PM<sub>2.5</sub> concentrations on the platforms were higher during the colder than the warmer period due to the seasonal changes in the ventilation settings. The PM produced in the tunnels is frequently transported into the platform by the trains motion, being easily trapped and accumulated. The new subway lines with platform screen doors showed PM<sub>2.5</sub> concentrations lower than those in the conventional system, due to more advanced ventilation set up, but also to lower train frequency and the design of the stations. PM concentrations inside the trains were generally lower than those on the platforms, attributed to the air conditioning systems operating inside the trains, which are equipped with air filters.

#### WE418

##### **Implementing Methodologies and Practices to Reduce air pollution Of the subway environment - IMPROVE LIFE**

**T. Moreno**, Geosciences; E. de Miguel, TMB; X. Querol, Institute of Environmental Assessment and Water Research IDAEA-CSIC; M. Capdevila, S. Centelles, TMB; V.I. Martins, Institute of Environmental Assessment and Water Research (IDAEA-CSIC); M. Minguillón, C. Reche, IDAEA CSIC Barcelona  
The greatest 21st century challenge to air quality in our cities is the pollution produced by road traffic. In contrast, underground rail systems provide an environmental urban lifeline, enabling large numbers of people to commute through the city efficiently and without contaminating the air in the streets above. However, the question arises: we know that city outdoor air is contaminated, but how clean is the air breathed underground? How much does the traffic pollution reach down into the metro tunnels and stations? How much does the movement of the trains themselves contribute to the inhalable particulate loading in the tunnels and platforms? The question of air quality in underground rail transport is not trivial: hundreds of millions of commuters in cities across the world use such systems daily, so any improvement in platform and train air is likely to produce significant health benefits. In this context, the European Union has recently awarded the IMPROVE (Implementing Methodologies and Practices to Reduce air pollution Of the subway environment) LIFE project to the Air Quality Research Group at IDAEA-CSIC, and the local transport authority Transports Metropolitans de Barcelona (TMB) with the clearly defined objective of providing local and national transport authorities of European countries with a protocol for recommended measures to enable them to reduce concentrations of particulate matter and improve air quality in metro platforms and trains. The results obtained so far indicate that air quality in stations is highly variable, depending on the complex interplay of such factors as station design and ventilating systems, and even the chemistry of brake pads used by the trains. Train frequency, number of people on the platform, depth of the station and its access to traffic-contaminated streets above

all additionally affect air quality. IMPROVE LIFE will produce an air mitigation strategy document appropriate for underground transport systems, and distribute it to transport authorities across the world. Apart from the obvious relevance to Europe, where around 60 cities have underground rail systems, the CSIC group is particularly interested in communicating their findings to countries in east Asia, notably Japan, South Korea, and China which is rapidly building new metro systems in its megacities. **Keywords:** subway PM, platform and train air quality. **Acknowledgements:** IMPROVE LIFE project (LIFE13 ENV/ES/000263) is funded by the European Community.

#### WE419

##### **Air quality in old and new subway systems of Barcelona from analysis of organic tracer compounds**

**B.L. van Drooge**; J.O. Grimalt, Environmental Chemistry; V.I. Martins, Institute of Environmental Assessment and Water Research (IDAEA-CSIC); T. Moreno, Geosciences; M.C. Minguillón, CSIC; X. Querol, Institute of Environmental Assessment and Water Research IDAEA-CSIC; L. Navarromartin, CSIC; B. Pina, IDAEA-CSIC / Environmental Chemistry

This work presents the analysis of organic molecular tracer compounds in PM<sub>2.5</sub> samples collected at 4 subway platforms of the Metropolitan area of Barcelona during 2013 and 2014. Whereas the platforms of Joanic, Santa Coloma and Tetuan stations belong to the old conventional system, Llefià is part of the new system. The subway in Llefià is a single tunnel with one rail track separated from the platform by a wall with mechanical doors (PSDs) that are opened simultaneously with the train doors. It includes advanced platform ventilation systems and has driverless train with optimised speed, braking and stopping controls. PM<sub>2.5</sub> samples were collected on quartz microfiber filters by means of a high volume sampler that was situated on the platforms. The filter samples were analysed following a described procedure. 40 organic molecular tracer compounds were quantified in the PM<sub>2.5</sub> samples, including toxic compounds, such as PAH, but also source-specific compounds, such as those from traffic, fragrances, tobacco smoke, wood burning, plastics and dust. Multi-variance analysis of the data base resolved five emission sources. The organic aerosol (OA) at the conventional stations were dominated by primary combustion sources in summer (45-80% of OA), while the OA in the new station was dominated by plasticizers (70% of OA) probably from the building material. Samples collected in winter showed contribution of outdoor biomass burning in all stations from 50% of OA in the stations further away from the city center, while the contribution was < 10% in the city center. In this period also the contribution of indoor dust mixed with fragrances was playing a substantial role in OA contributions in two conventional stations (30% of OA). The results showed large season and spatial variability among the stations, although generally, the station of the new subway system showed lowest levels of organic compounds, as well as lowest responses in complementary biological tests (fish embryo toxicity). These tests showed relatively mild toxic effects, and biological responses only related to combustion sources and dioxin-like compounds, which had higher contributions in the older subway systems.

#### WE420

##### **ASSESSMENT OF RESPIRABLE PARTICULATE MATTER IN ISTANBUL SUBWAY SYSTEM**

**U. Alver Sahin**, Environmental Engineering Department; B. Onat, Istanbul University / Environmental Engineering Department

Previously conducted studies investigating the relationship between particulate matter and daily mortality indicated that passengers are exposed to this risk in the short and the long term due to the endangerment of their health. People spend most of their time indoors; either at home, or in the workplace. One of the places with elevated risk of dust exposure is the transportation system. The underground transportation system is one of the convenient modes of transportation in many metropolitan cities. In this study, PM<sub>10</sub> concentrations, as well as the size distributions of Fe-containing and Cu-containing particles were measured for weekly periods of 7 days throughout 24-h in 6 subway stations of the underground transportation system in Istanbul. The average daily PM<sub>10</sub> concentrations were determined as 85.7  $\mu\text{g}/\text{m}^3$ , 136  $\mu\text{g}/\text{m}^3$  and 240.9  $\mu\text{g}/\text{m}^3$  at three stations in line M2: 4. Levent, Sisli and Taksim, respectively and as 67.8  $\mu\text{g}/\text{m}^3$ , 58.6  $\mu\text{g}/\text{m}^3$  and 112.8  $\mu\text{g}/\text{m}^3$  at three stations in line M1: Airport, Otogar and Aksaray, respectively. PM<sub>10</sub> concentrations that were monitored in the underground metro stations were significantly higher ( $p < 0.01$ ) than those that were monitored in the urban air quality stations. The average Fe and Cu concentrations in total PM were 10.3-28.2  $\mu\text{g}/\text{m}^3$  and 134.7-325.4 ng/m<sup>3</sup>, respectively at the stations of M1 line. The relative abundance of Fe-containing particles among the particles of size >2.1  $\mu\text{m}$  collected in line M1 metro stations was determined as 15-30%, which is 3.5-8 times higher than the abundance determined in the Istanbul atmosphere.

#### WE421

##### **Effect of depth in the Air Quality of a Mexican Subway**

**V. Mugica**, Universidad Autonoma Metropolitana / Basic Sciences; J.M. Murcia, O. Hernández, A.A. Neria, Universidad Autonoma Metropolitana-Azcapotzalco  
Tacubaya subway station, located close to downtown of Mexico City, was selected to conduct a study to determine the presence and metal content of fine particles at different seasons and platforms' depths. In this station, three lines have correspondence: Line 9 at 10 m depth, Line 1 at 25 m depth and Line 7 at 40 m

depth. Monitoring campaigns using High Vol samplers were carried out in dry-cold and dry-warm seasons. PM<sub>2.5</sub> concentrations in line 9 were 67 and 68 µg/m<sup>3</sup> during dry-cold season and warm dry season respectively; in line 1 were 99 and 108 µg/m<sup>3</sup> respectively, and finally 107 and 126 µg/m<sup>3</sup> station in line 7. The PM<sub>2.5</sub> inside the platforms presented concentrations between 9 and 100% higher than outside. Statistical analysis showed significant difference among Line 9 and the other two Lines (1 and 9) with different depths, but there was not significant differences between cold-dry and warm-dry season, although in general higher concentrations of PM<sub>2.5</sub> were measured in the warm-dry season. The analysis of particle showed high concentrations of iron, copper, chromium, and zinc which can contribute to oxidative stress in cells.

### WE422

#### The characterisation factor for freshwater and sediment ecotoxicity potential of releases of ENM

B. Salieri, EMPA / C.I.R.S.A.; R. Hischier, EMPA / Technology and Society Lab  
The importance of LCA in the field of engineered nanomaterials (ENMs) has been emphasized by several researches and reports. However, to date only a few LCA studies on ENMs have been carried out, and few of them have actually assessed aspects related to toxicity of releases of ENMs (Hischier et al., 2012; Miseljic and Olsen, 2014). This is mainly due to lack of respective characterisation factors (CFs) for this kind of releases in the various impact assessment methods in use. The present study aims to provide CFs for the freshwater and the sediment ecotoxicity potential of carbon nanotubes (CNTs) and nano-TiO<sub>2</sub>. The USEtox model is selected as characterization model for the impacts in the area of ecotoxicity. Within this model, the freshwater ecotoxicity CF (PAF m<sup>3</sup> day kg<sup>-1</sup>) of a chemical is comprised by a fate factor (FF), an effect factor (EF), and an exposure factor (XF). Currently, the USEtox model does not take into account the compartment of sediment, so no CF for this impact category exists so far, although the framework may be suitable for this additional compartment. As described in Salieri et al., 2015 USEtox may also be applied to calculate the CF for ENMs. In order to account for nano-specific environmental fate processes the current USEtox model needs to be adjusted. Then USEtox applies an approach based on partitioning coefficients to calculate the FF, whereas for ENMs this approach may lead to erroneous results, since kinetic rate constants have been considered to be more representative of the environmental fate processes of ENMs (Praetorius et al., 2014). Therefore, on the basis of recent studies (Salieri et al., 2015; Meester et al., 2014) the CF for sediment and for nano-TiO<sub>2</sub> is calculated by accounting the FF in sediment compartment and by including into the EF calculation the toxic effect to benthonic organisms. Secondly, this approach is applied also for releases of CNTs. A CF for CNTs, based on the original USEtox fate model, has been already published (Eckelman et al., 2012). In opposite to this publication, here the kinetic rate constant is used to calculate the fate of CNTs in the environment. In conclusion, the study (1) describes a more adequate framework for the fate analysis of releases of ENMs, (2) applies this framework and calculates CFs for freshwater and sediment ecotoxicity of nano-TiO<sub>2</sub> and CNT in order to increase the number of CF for ENM, and thus allow an accurate evaluation of potential impacts of releases of ENMs.

### WE423

#### Assessing the relevance of engineered nanoparticles in freshwater ecotoxicity for life cycle impact assessment

C. Alfonsín, Chemical Engineering; R. Sierra-Alvarez, University of Arizona / Chemical and Environmental Engineering; G. Feijoo, M. Moreira, University of Santiago de Compostela / Chemical Engineering  
The term “emerging contaminants” comprises all those chemicals which are not usually monitored in the environment, even though they could lead to toxicological effects in aquatic organisms. Micropollutants, such as pharmaceuticals and personal care products (PPCPs), and engineering nanomaterials, such as nanoparticles (NPs), stand out in this group. Life cycle assessment (LCA) is the recommended methodology to carry out the environmental evaluation of products and processes. The inclusion of NPs in LCA studies is relevant in toxicity related impact categories but requires characterisation factors (CFs), which are lacking so far. In this work, three target NPs were chosen for the calculation of CFs: n-Al<sub>2</sub>O<sub>3</sub>, n-CeO<sub>2</sub> and n-SiO<sub>2</sub> with different particle size. Therefore, the first step for the toxicological assessment was the calculation of CFs by means of USEtox methodology. Among the input parameters needed for the calculation, special attention was paid to the ecotoxicological parameters: EC50 and LC50, because of the size-dependent toxicity observed for NPs. Freshwater CFs outcomes depended on the size, the higher the NP, the lower the CF. For a practical application, the environmental performance of the treatment of municipal wastewater containing HMs, PPCPs and n-CeO<sub>2</sub> in a conventional activated sludge (CAS) reactor was assessed. The direct discharge of the influent into the environment led to 19.86 CTUe m<sup>-3</sup> where 25% was attributed to the release of n-CeO<sub>2</sub>. The CAS implementation led to a reduction around 91% of the total impact mainly due to the removal of HMs and emerging contaminants from wastewater. The addition of NPs to toxicological assessments was found to be relevant considering that their associated burdens are two times higher than those for PPCPs. Moreover, it was demonstrated the concentration of NPs found in wastewater effluents after an efficient removal would lead to very low

values for freshwater ecotoxicity for NPs after treatment.

#### Multi-Criteria Decision Analysis assessment of Sustainable Nanotechnologies

A. Zabeo; v. subramanian, Ca Foscari University of Venice / Dept of Environmental Sciences Informatics and Statistics; E. Semenzin, Ca Foscari University of Venice / Department of Environmental Sciences Informatics and Statistics; D. Hristozov, Ca Foscari University of Venice; I. Linkov, US Army Engineer Research and Development Center; A. Marcomini, University of Venice / Department of Environmental Sciences Informatics and Statistics  
The adoption of Engineered Nanomaterials (ENM) in the production of everyday goods is constantly increasing all over the world generating therefore a growing attention for sustainable nanotechnologies. Sustainability requires the assessment of many different aspects related to the production, use and disposal of Engineered Nanomaterials like ecological and human health risks, environmental impacts, as well as costs and benefits of nano-products. Sustainability can be improved by selecting the most effective risk management alternatives (e.g. safety by design technological alternatives, personal protective equipment) taking into consideration the aforementioned multiple aspects of evaluation. The presented Multi-Criteria Decision Analysis assessment methodology is aimed at aiding decision makers in the selection of effective management measures and technological alternatives for risk reduction by properly integrating results coming from the application of the most up to date methodologies related to the evaluation of ecological and human health risks (risk analysis, RA), environmental impacts (Life Cycle Assessment, LCA), costs as well as benefits of nano-products (Cost Benefit Analysis CBA) in the light of decision maker's preferences. The presented methodology has been developed in the frame of the European Commission's FP7 framework project SUN (<http://www.sun-fp7.eu/>) that aims at developing a comprehensive framework, assessment methodology and Decision Support System (DSS) software for the evaluation of sustainable nanotechnologies.

## Managing nanomaterials in the environment: lessons learnt to date, state of the art and future perspectives (P)

### WE426

#### Integrated discriminant biomarker analysis as a tool to reveal the effects of metallic nanoparticles on the freshwater mussel *Dreissena polymorpha* following mesocosm exposures

M. Garaud, Laboratory LIEC - CNRS UMR 7360 - UdL / CNRS UMR; S. Devin, LIEC - Université de Lorraine - CNRS / LIEC CNRS UMR; V. Felten, LIEC; M. Auffan, iCEINT / International Consortium for the Environmental Implications of Nanotechnology; C. Bertrand, Université de Lorraine, CNRS UMR 7360; C. Pagnout, Université de Lorraine; S. Pain-Devin, Université de Lorraine - UL / LIEC CNRS UMR; F. Rodius, Université de Lorraine; B. SOHM, P. Rousselle, LIEC - Université de Lorraine - CNRS; M. Tella, CEREGE; P. Wagner, LIEC CNRS Université de Lorraine; L. Giamberini, Université de Lorraine, CNRS UMR 7360 / LIEC CNRS UMR

Metallic nanoparticles (NP) are among the most widely used NP, notably silver NP (nAg) for their antibacterial properties, and ceria NP (nCeO<sub>2</sub>) for their catalytic and anti-UV properties. As environmental exposure is increasing, the importance of assessing nanoparticle ecotoxicity in environmentally relevant conditions has been stressed, but the ecotoxicity testing often focused on acute toxicity assessment using standardized protocols and species. Yet, multibiomarker approaches have been shown to be useful for detecting early impacts of stressors on organisms. However, the analysis and synthesis of the complex biomarker dataset can be difficult and need powerful integrated biomarker analysis tools. In our works, we assessed the sub-lethal effects of nAg and of nCeO<sub>2</sub> on the freshwater mussel *Dreissena polymorpha* in two distinct experiments. Experiments were conducted in small (56L) mesocosms simulating simplified lotic ecosystems with the presence of a natural bacterial community and of three species of green algae. Tanks were chronically contaminated with the NP during 4 weeks to reach nominal concentrations of 1 mg/L of nCeO<sub>2</sub> and 50 µg/L of nAg at the end of the experiment. The fate of and effects of NP on mussels were measured using a multibiomarker approach. We then performed a linear discriminant analysis on the biomarker data in order (i) to define if the main experimental conditions led to different patterns of biological responses and (ii) to select the minimal battery of biomarkers that allow identification of the exposure condition. In both nCeO<sub>2</sub> and nAg experiments, discriminant analysis allowed us to clearly separate experimental conditions. The biomarker datasets were reduced from 24 to 9 for nCeO<sub>2</sub> and to 10 for nAg exposures. Using two discriminant functions with these reduced sets of biomarkers, we were able to evidence effects of both NP on mussels. Moreover, on the four most discriminative biomarkers (p < 0.05) of each experiments, three were common between nCeO<sub>2</sub> and nAg exposures, namely gill MT and GSTpi mRNA expressions, and haemocyte lysosomal morphology. It suggests that these biomarkers could be of primary interest in future nanoparticle ecotoxicity assessment. As a whole, the impacted biomarkers were more indicative of an exposure to NP, while toxic effect biomarkers were largely unaffected, suggesting that these metallic NP would not exert significant toxicity on mussels exposed in environmentally realistic conditions.

#### Obtaining an Overview of the Environmental and Human Risk Potential of Pesticides in a global perspective based on currently available Data - a Literature Review Study

F. Weiss, Eawag - Swiss federal Institute of Aquatic Science and Technology / Department of Environmental Chemistry; C. Zurbrügg, Eawag Swiss Federal Institute of Aquatic Science and Technology / Department of Water and Sanitation in Developing Countries; R.I. Eggen, Eawag / Department of Environmental Toxicology; C. Stamm, Department of Environmental Chemistry

Today, pesticides are intensively used in agriculture across the globe. Worldwide about  $2.4 \cdot 10^6$  tons of pesticides are used annually on  $1.6 \cdot 10^9$  ha of arable land. This yields a global average use of pesticides of 1.53 kg/ha year. In future, the use in the agricultural sector will continue to grow. Recently, it was estimated that within the last decade, the world pesticide market increased by 93% and the Brazilian market alone by 190%. Though pesticides are intensively used, scientifically sound data of pesticide use are still lacking or not available. Furthermore, current agricultural practices often do not consider sound approaches of pesticide application. Therefore it is highly relevant to: i) identify risk areas where pesticides affect environmental and human health; ii) understand the environmental behavior of pesticides in vulnerable ecosystems; and iii) to develop possible mitigation options to reduce their exposure to ecosystems and humans. Information was collected from scientific literature, reports and webpages of specialized organizations and NGOs to obtain a comprehensive overview on the environmental burden of pesticides. Available data show that the highest annual application rates of pesticides, range from 5 to 76 kg/ha arable land, are found in El Salvador, Bolivia, Malaysia, Guatemala, Ecuador, Jordan, Panama, Belize, China, Suriname, North Korea, Colombia, Costa Rica, Mauritania and the Bahamas. Tropical areas thus seem to be important "hot spots" of pesticide use. Nevertheless, especially in low and middle income countries (LAMICs), the available data on pesticide use are not comprehensive enough to obtain an overall picture of the associated risks at global scale. However, literature evidence from single studies show high impacts on environmental and human health. Internationally banned pesticides are still often used or stockpiled under unsafe conditions in LAMICs. Furthermore, low skills and knowledge of workers on sound pesticide use, storage and handling is widespread. From the human risk perspective it is estimated that around 3 million people suffer from severely pesticide poisoning worldwide. A project has recently been initiated with a focus on assessing pesticide exposure of the aquatic environment and humans in tropical catchments of LAMICs. Other aims of this follow-up project are to assess hazards of pesticide exposure and to suggest mitigations options to reduce exposure to pesticides.

### TH002

#### Agricultural impact on water quality and ecosystems of the lower Tempisque River basin, Costa Rica

E. de la Cruz, Universidad Nacional / IRET; M. Pinnock Branford, Universidad Nacional / Instituto Regional de Estudios en Sustancias Tóxicas; S. Echeverría, Instituto Regional de Estudios en Sustancias Tóxicas; F. Mena, Universidad Nacional / Instituto Regional de Estudios en Sustancias Tóxicas; C. Barata, CSIC / Environmental Chemistry; C. Ruepert, Universidad Nacional / IRET

This project assesses the effects of contaminants from agriculture (rice, sugar cane and pasture) on the habitat, structure and function of wetland communities in the lower Tempisque River Basin, located in the Pacific of Costa Rica. Between 2009 and 2012 a program that monitored the presence of pesticides and nutrients in surface water at nine sites in the area, which were classified from severely to little affected, was done. Four of these sampling points (2 of reference and 2 impacted) also have information on acute and chronic toxicity to aquatic organisms, on biomarkers (GST, LPO y AChE in muscle and brain) in field exposed fish (*Poecilia gillii*); of *Daphnia magna* feed rate changes after 24 hrs field exposure; of the macrobenthic and plant community structure changes and over 30 physicochemical parameters, including pH, conductivity, Dissolved oxygen, nutrients and grain size sediment. Residues of ametryn, terbutryn, butachlor, dimethoate, diuron, epoxiconazole, propiconazole, tebuconazole, triazophos, cypermethrin, endosulfan-b and hexazinone pesticides water were determined in surface water. At sites where the water enters to the area (little or less contaminated) the contamination was lower or nonexistent and at the areas influenced by crop production contamination by pesticides and nutrients were increased. Changes were observed in the feeding rate of daphnia, in biomarkers responses and biotic communities' indices; some associated with pollution. In macroinvertebrates, the disappearance of families such as Perlidae and Platystictidae, which are at little affected site; and an increase in the abundance of molluscs and oligochaetes and the appearance of families Caenidae, Glossosomatidae, in severely affected one. Something similar happened with the algal community. Macrophyte species richness and amphibious plants were higher at sites with high content of organic matter and backwaters. The estimated risk for aquatic organisms of some pesticide residues concentrations in surface waters reveals a problem. Most of them were over the security indicator to protect diversity and ecosystem processes.

### TH003

#### Effects of pesticide residue presence on the establishment of macroinvertebrate communities in a tropical stream in South Pacific Costa Rica

S. Echeverría, Instituto Regional de Estudios en Sustancias Tóxicas; C. Ruepert, Universidad Nacional / IRET

The Volcán River watershed is a system of rivers and streams whose headwaters are located in the La Amistad International Park, a UNESCO World Heritage Site, in the South Pacific of Costa Rica. Outside of the Park, these rivers and streams cross small urban settlements, cattle fields and agricultural land (mostly pineapple and sugar cane) until they drain into the Río General. The quality of its waters was assessed each trimester from December 2011 to March 2013, by means of physical-chemical parameters (pH, conductivity, temperature, DO, DBO, nitrate, total and soluble P, pesticide residue analysis) and macroinvertebrate (MI) sampling in eight sites across the watershed (Volcán, Cañas and Ángel rivers, Peje and Maura streams). Water quality in these rivers is very good or excellent according to the BMWP index (modified for Costa Rica) and they also present a tremendous biological diversity. However, Peje Stream is especially vulnerable to pollution because it drains agricultural lands in its entire path and has almost no riparian forest to function as a buffer. This stream has significantly higher nitrate ( $6.8\text{--}17\text{ mg/l}$ ) and conductivity ( $59\text{--}70\text{ }\mu\text{S/cm}$ ) than all the other rivers in the watershed. Additionally, pesticides have been detected since 2001 in Peje Stream in very similar concentrations than the ones found in the present study ( $\sim 6\text{ }\mu\text{g/l}$  of bromacil and  $\sim 0.05\text{ }\mu\text{g/l}$  of diazinon). This indicates that MI inhabiting Peje Stream must have some degree of tolerance to pesticides. It is noteworthy that some of the families composing the community year round (Hydropsychidae, Baetidae, Elmidae) are not typically classified as tolerant and, also, there is a marked seasonal variation in the abundance of other intolerant families such as Leptohyphidae, Leptophlebiidae (Ephemeroptera), Philopotamidae, Glossosomatidae, Hydroptilidae (Trichoptera), Corydalidae (Megaloptera), whose presence is limited exclusively to the dry season (December to April). The characteristics of the watershed, with large areas of forest and excellent water quality allow for the re-colonization of organisms into Peje Stream, however, those organisms are incapable of developing and growth in this stream, providing evidence of a chemical barrier for the establishment of these species during the rest of the year. This investigation represents an approximation to the study of tolerance of tropical MI to the prolonged presence of pesticides and nutrients in water.

### TH004

#### Glyphosate and AMPA distribution in Suquia river basin: an ecotoxicological risk assessment.

R. Bonansea, Universidad Nacional de Córdoba / Facultad de Ciencias Químicas; I. Filippi, Universidad Nacional de Córdoba; D. Marino, Universidad Nacional de La Plata; D.A. Wunderlin, Universidad Nacional de Córdoba / ICYTAC DPTO QUÍMICA ORGÁNICA FACULTAD DE CIENCIAS QUÍMICAS; M.V. Ame, Universidad Nacional de Córdoba- CONICET / Bioquímica Clínica

Glyphosate is the most widely used herbicide worldwide, in order to evaluate the occurrence of this pesticide and its microbiological degradation product, the aminomethylphosphonic acid (AMPA), this study measured their presences in freshwater, sediments and suspended particulate matter (SPM) samples from Suquia River basin in Córdoba, Argentina. From all the analyzed samples 35 % contained glyphosate, AMPA or both compounds. The concentrations were spread in different percentages depending on the environmental matrices considered, ranging from 12 to 20 times higher of glyphosate and AMPA in sediment and SPM than in water. The maximum concentrations found in water were  $125\text{ }\mu\text{g. l}^{-1}$  of glyphosate and  $4.8\text{ }\mu\text{g. l}^{-1}$  of AMPA, in sediment  $1882.3\text{ }\mu\text{g. kg}^{-1}$  and AMPA  $266.1\text{ }\mu\text{g. kg}^{-1}$  and in SPM  $1570.7\text{ }\mu\text{g. kg}^{-1}$  of glyphosate and  $684.9\text{ }\mu\text{g. kg}^{-1}$  of AMPA. The most polluted area came to be CM that is situated in a green belt zone, in second place are RP and SR, extensive agricultural areas. As regards the aquatic risk assessment in water and sediments, fish in LC and CM are threatened by the concentrations of glyphosate in water; these values were below the levels of concern for wildlife however it is convenient to update the limits established for freshwater aquatic protection.

### TH005

#### Multiple biomarkers response in the fish Prochilodus lineatus caged in rivers in agricultural areas: a case study in Parana state (Southern Brazil)

C.D. Vieira, Universidade Estadual de Londrina; P.G. Costa, FURG / Escola de química e alimentos; B. Lunardelli, Universidade Estadual de Londrina; L.F. Oliveira, Universidade Estadual de Londrina / Ciências Fisiológicas; W.E. Risso, Universidade Estadual de Londrina; P. Meletti, C.B. Martinez, Universidade Estadual de Londrina / Ciências Fisiológicas

The Northern Parana region stands out in the Brazilian agricultural scenario, resulting in the intensive use of pesticides and the reduction of the natural vegetation, leading to the contamination of the aquatic ecosystem and its biota. Thus, the main objective of this study was to analyze biomarkers in fish caged in two streams subject to pesticides input (Apertados - AP and Jacutinga - JC) and in a reference stream, located in a forest fragment (Godoy stream - GD), in order to assess the quality of these streams and the influence of contaminants on the biological responses of fish. Juveniles of *Prochilodus lineatus* were submitted to *in situ* tests in AP, JC and GD for 96 h. Biochemical parameters such as the activity of 7-ethoxyresorufin O-deethylase (EROD), glutathione S-transferase (GST) and

acetylcholinesterase (AChE), the content of non-protein thiols (NPSH) and the occurrence of lipid peroxidation (LPO) and protein carbonylation (PCO) were evaluated in different tissues. In addition, genotoxic biomarkers, such as DNA damage and the occurrence of micronuclei and nuclear erythrocytic change (ENAS), were analyzed in blood cells. The results of the biomarkers were integrated in the "Index of Biomarker Response" (IBR). Samples of water and sediment were analyzed for metals and pesticides. Higher GST activity was observed in the liver and gills of fish caged in AP and in JC, respectively. It was also observed increased LPO in the liver of fish caged in AP and JC. On the other hand, lower AChE activity was observed in the brain and muscle of fish caged in AP and JC. These animals also showed higher scores of DNA damage and occurrence of ENAS in comparison with fish caged in GD. Several pesticides were found in water in concentrations higher than the limits set by the Brazilian guidelines, highlighting DDT, DDE, DDD, HCH, heptachlor, dichlofluanid and aldrin. The AP stream showed the highest concentrations of the measured compounds, followed by JC and GD. According to IBR results ( $AP\ 21.7 > JC\ 18.5 > GD\ 12.6$ ), AP and JC streams showed the poorest environmental quality, corroborating the chemical analysis of the water and sediment, while GD showed a lower degree of contamination, probably related to the protection of the natural vegetation. By means of the integrated analysis of biomarkers, it appears that the changes in biomarkers correlated well with the levels of environmental contaminants, demonstrating that this approach is suitable for biomonitoring.

#### TH006

##### **Assessing Pollution in Marine Protected Areas: The role of a multi-biomarker and multi-organ approach**

P. Gusso Choueri, Universidade Estadual Paulista UNESP; R.B. Choueri, Universidade Federal de São Paulo; G. Araujo, Universidade de Aveiro / Biologia; A.F. Cruz, Universidade Estadual Paulista UNESP; T. Stremel, S. Campos, Universidade estadual de ponta grossa UEPG; C.A. Ribeiro, Universidade Federal do Paraná; D. Abessa, Unesp / Marine Biology and Coastal Management  
Marine Protected Areas (MPAs) are vulnerable to many natural and anthropic pressures, including pollution. However, environmental quality monitoring in these areas traditionally has relied on water chemistry and/or microbiological parameters. The goal of the current study was to investigate the role of a set of biomarkers (GPx, GST, GSH, DNA damage, LPO, AChE and condition index) in different target organs (liver, kidney and gills) of a demersal native fish in order to assess the environmental quality of a subtropical MPA - the Environmental Protected Area of Cananeia-Iguape-Peruibe (APA-CIP), located in southern Brazil. Arsenic and metal body burdens were quantified on liver and muscle (Cu, Mn, Zn, Cr, Co, Ni, Cd, Pb), and PAHs metabolites were identified in bile. The catfish (*Cathorops spixii*) is widely consumed by the local population and was used as bioindicator species; the results were integrated by the use of multivariate analysis. The use of the biomarker approach allowed for the identification of both seasonal and spatial variations in pollution sources around the APA-CIP. The current study shows that rainfall seasonality plays an important role in the estuarine pollution of the APA-CIP in terms of risks to the biota. The evidence includes the association of biomarker responses in target tissues with metal burdens in muscle and liver tissues and PAH levels in the bile of *C. spixii*. Higher metal body burdens associated with biological responses were found in the sites under the influence of urban areas during the dry season, and they were found in the sites under the influence of the Ribeira de Iguape River (RIR) during the rainy season. The liver was found to be more responsive in terms of its antioxidant responses, whereas gills were found to be more responsive to biomarkers of effect. These results show that this set of biomarker analyses in different organs of fish is a useful tool for assessing chemical pollution in an MPA. This study adds to the knowledge on the effectiveness of MPA management. Such tools provide information for making sound decisions regarding environmental health status in vulnerable or valuable marine areas, and they support the management of MPAs and policies for conservation.

#### TH007

##### **The role of a multi-biomarker approach in crab within an integrated sediment quality assessment in a Marine Protected Area**

G. Araujo, Universidade de Aveiro / Biologia; P. Gusso Choueri, L.B. Moreira, Universidade Estadual Paulista UNESP; D. Abessa, Unesp / Marine Biology and Coastal Management

Estuarine and marine Protected Areas (PAs) may be vulnerable to anthropic pressures, as the contaminants introduced through the continental drainage. This study aimed to evaluate if sediments from the Cananeia-Iguape-Peruibe Protected Area (named APA-CIP) are contaminated by metals at levels that negatively affect the biota. Six sampling sites were established along the estuary and sediments and blue crab individuals (*Callinectes danae*) were collected. To accomplish that it was performed geochemical analyzes, ecotoxicological assays (embryonic development of *Lytechinus variegatus*, reproduction of *Nitocra* sp. and survival of *Tiburonella viscana*) and biomarkers (Glutathione S-transferase (GST), Reduced Glutathione (GSH), Glutathione peroxidase (GPx), Acetylcholinesterase (AChE), Metallothioneins (Met), DNA damage and Lipid peroxidation (LPO)) on anterior and posterior gills, hepatopancreas and muscles. Results showed correlations between GPx and GSH in posterior gill, GPx with GST and GSH with LPO in anterior gill and GPx with GST and MT with LPO in hepatopancreas. For posterior gill, GST correlated with toxicities (*L. variegatus* and *T. viscana*), whereas LPO

correlated with Ba, Pb and U in sediments. In hepatopancreas tissue, MT correlated with *T. viscana* mortality and LPO correlated to the toxicities (all tests). Results suggest that posterior gill and hepatopancreas are more sensitive to environmental contamination, which is consistent with their respective functions and contaminants type. Some biomarkers responses seemed to better respond to natural/seasonal factors (such as AChE and DNA damage); however GPx, GST, GSH and LPO seemed to better address effects of contamination or its interaction with natural stressing factors. The results suggest that the principal exposure to contaminants are through posterior gill (dissolved metals), with a subsequent role of hepatopancreas in depuration of contaminants.

#### TH008

##### **Biochemical and genotoxic biomarkers in the Neotropical fish *Prochilodus lineatus* caged in a river contaminated by tannery effluents**

B. Lunardelli, M.T. Cabral, C.D. Vieira, Universidade Estadual de Londrina; L.F. Oliveira, Universidade Estadual de Londrina / Ciencias Fisiologicas; W.E. Risso, Universidade Estadual de Londrina; P. Meletti, C.B. Martinez, Universidade Estadual de Londrina / Ciencias Fisiologicas

The objective of this study was to analyze biochemical and genotoxic biomarkers, as well as to determine chromium levels, in different tissues of the Neotropical fish *Prochilodus lineatus* submitted to *in situ* tests in Bandeirantes do Norte river (Parana State, southern Brazil), which receives tannery effluents. Juveniles of *P. lineatus* were submitted to *in situ* tests at four different river locations: site A – upstream of the tannery; site B – next to the tannery; and sites C and D – downstream of the tannery. After 96 h of cage confinement, samples were collected from fish tissues, river water, and river sediments in order to quantify chromium levels. In addition, tissue samples were used to assess the activity of ethoxoresorufin-o-deethylase (EROD), glutathione S-transferase (GST), and acetylcholinesterase (AChE), the content of glutathione (GSH), metallothionein-like proteins (MT) and lipid peroxidation (LPO), and DNA damage levels by the comet assay. Higher chromium concentrations were detected in the water and sediments from site B and in the liver of fish confined at site B compared to the other locations. Fish caged at site B also showed higher levels of MT and EROD activities in their livers, in comparison to the fish caged at the other sites. Moreover, fish at site B had increased liver and branchial GST activities, as well as higher GSH concentration in the liver, than fish caged at site A. There were no statistically significant variations in LPO, DNA damage and brain or muscle AChE activity. These results indicated that tannery effluents increased chromium levels in the water, sediments, and fish livers and stimulated the synthesis of MT and GSH and the activities of EROD and GST. In conclusion, tannery effluents compromised the quality of the river water despite previous treatment, which resulted in altered biochemical markers and chromium accumulation in animals exposed to this river.

#### TH009

##### **WATER AND SEDIMENT TOXICITY IDENTIFICATION AND EVALUATION OF A TROPICAL URBAN RESERVOIR**

A.C. Rietzler, Department of General Biology; C. Botta, University / CRHEA; M.M. Martins Ribeiro, Department of General Biology  
Pampulha reservoir, a urban eutrophic system located in Belo Horizonte, Minas Gerais, Brazil, has been studied from a limnological point of view for many years, showing high inputs of domestic and industrial effluents from its tributaries. Ecotoxicological studies which began about 15 years ago, also showed acute and chronic toxicity effects of water and sediments on *Daphnia similis* and *Ceriodaphnia silvestrii* used as test-organisms (ABNT 2004a; 2005a). More recently, an attempt to identify contaminants involved in water and sediment (interstitial water) acute toxicity effects was made in 2011 and 2012 (TIE-phase I, USEPA, 1991), indicating non-polar organic and filterable compounds, as well as oxidant compounds as water contaminants and ammonia as sediment contaminant. Focusing on the water TIE approach, preliminary toxicity assays with water samples collected in June 2014 showed again water acute toxic effects only on *Daphnia similis*. TIE experiments conducted afterwards, mainly indicated, again, effects of non-polar organic and filterable compounds, which were attributed to cyanobacteria cells and toxins. The specimens tested could recover from immobility effects after being transferred to culture water, corroborating neurotoxic effects of cyanobacteria (*Cylindrospermopsis raciborskii* and possibly *Planktothrix* sp). Besides that, sonification of filters containing water particulate organic matter and testing showed recovering of toxicity effects on *Daphnia similis* and on *Ceriodaphnia silvestrii*, which initially did not show water toxicity effects. In this case, probably the broken cyanobacteria cells exposed even more toxins to the organisms tested, which effects were basically associated to ingestion by *D. similis* and not by *C. silvestrii*.

#### TH010

##### **The joint effect of chlorpyrifos and fenobucarb on acetylcholinesterase in climbing perch (*Anabas testudineus*).**

T.T. Nguyen Thanh, Stockholm University / fisheries; H. Berg, Orebro University; N.H. Pham, C.V. Nguyen, Can Tho University / College of Environment and Natural Resources

Climbing perch (*Anabas testudineus*, Bloch, 1792), is an important food fish to local people in the Mekong Delta. Although no official statistic, the wild population

of climbing perch has declined during the recent years. Organophosphates, such as chlorpyrifos, and carbamates, such as fenobucarb, are commonly used to control a wide range of pests in rice fields. These pesticides are highly toxic to aquatic organisms due to their ability to inactivate the enzyme acetylcholinesterase. This study assesses the combined effect of chlorpyrifos and fenobucarb on brain acetylcholinesterase in climbing perch fingerlings from rice field in the Mekong Delta. After spraying the, the water concentrations of both pesticides were decreased quickly below detection levels within three days. However the inhibition of brain AChE activity continued for several more days. The result also indicates a quicker and less prolonged inhibition of brain AChE activity from the mixture than when the fish were exposed to only CPF.

#### TH011

##### Calculating herbicide sorption coefficients using selected soil properties in Brazilian tropical conditions

**K.F. MENDES**, Laboratory of Ecotoxicology; F.C. Reis, USPCENA / Lab Ecotoxicologia; v. tornisielo,

Herbicides play an important role in modern agriculture, but concerns about food safety and environmental impacts of herbicide residues have increased. Therefore, current mathematical models for predicting herbicide behavior in tropical soils use sorption coefficients ( $K_d$ ) and organic carbon affinity ( $K_{oc}$ ) obtained from temperate soils, indicating that the information obtained may be distorted. Moreover, organic matter content in tropical soils varies greatly when methods and laboratories are compared; consequently, those conditions cause  $K_{oc}$  values to vary. Thus, the objectives of this paper were to review the scientific literature for evaluate  $K_d$  and  $K_{oc}$  values of tropical soils using the values described in the databases for temperate soils, and correlate  $K_d$  values with tropical soil properties.  $K_{oc}$  values were calculated based on an OC/OM (organic carbon/organic matter) index of 0.54 for 22 herbicides. Pearson correlation was used to compare  $K_d$  values and soil properties (organic matter, OM; clay mineral, CM; potential hydrogen, pH and cation exchange capacity, CEC) for each herbicide in tropical soils. The results indicate that  $K_d$  and  $K_{oc}$  values for herbicides in tropical soils presented an OC/OM index ranging from 0.395 to 1.275. The  $K_d$  values of the majority of the herbicides correlate with the variation of OM and CEC contents in tropical soils. Research in Brazil is already generating information such as sorption coefficients, however, they are not tabulated in a database as has been done for temperate soils. Thus, it was possible to group the information related to  $K_d$  and  $K_{oc}$  values of herbicides in tropical soil conditions. Standardized values confer more precision and accuracy to the mathematical models when used to represent herbicide behavior in soils with similar properties to tropical soils.

#### TH012

##### Quantification of oxadiazon residues in soils samples using a system solid-liquid extraction with low temperature partitioning by high performance liquid chromatography

**K.F. MENDES**, Laboratory of Ecotoxicology; M.R. REIS, UFV / Agricultural SCIENCES INSTITUTE; v. tornisielo,

Herbicides are fundamental for improving the productivity of modern agriculture. However, they have caused concern regarding food security and the environmental impacts of herbicide residues. Surface and subterranean waters have been contaminated by agricultural and non-agricultural herbicide applications, as a result of the physico-chemical characteristics of the soil and of the herbicide. Adding organic residues to agricultural soils is a widely used practice to increase organic matter content and prolong herbicide persistence. However, half-lives are often determined in laboratory studies using disturbed soils, where the aggregates of the soil, micropores, macropores and the proportion of solution to solids differ from field soil conditions. The behavior of oxadiazon

(5-tert-butyl-3-(2,4-dichloro-5-isopropoxyphenyl)-1,3,4-oxadiazol-2 (3H)-one) in the soil may be influenced by organic material content. The objective of this study was to determine the oxadiazon residues by chromatography as a function of organic material and soil depth, with Oxisol, clay texture, in Rio Paranaíba, Minas Gerais State, Brazil. A randomized block design was used, with treatments arranged in a scheme of  $2 \times 4 \times 8 + 1$  subdivided plots with four repetitions. The plots were comprised of soil with organic matter incorporated ( $8 \text{ t ha}^{-1}$ ) and without organic material incorporated, and a control ( $0 \text{ t ha}^{-1}$  and  $0 \text{ g ha}^{-1}$  of oxadiazon). The subplots were the soil depths (0.00-0.05; 0.05-0.10; 0.10-0.15 and 0.15-0.20 m) and the subsubplots were soil collection time (0, 2, 4, 8, 16, 32, 64 and 128 days after application - DAA). Oxadiazon was applied at  $1 \text{ kg ha}^{-1}$ . For residue determination, samples were quantified with high performance liquid chromatography (HPLC) using the technique of solid-liquid extraction with low temperature partitioning (SLE-LTP). In the superficial layer of 0.00-0.05 m, dissipation  $t_{1/2}$  of oxadiazon was between 56 and 51 days in soil with and without organic material incorporated, respectively. Oxadiazon was found in the upper layer (0.00-0.10 m) of soil until 64 DAA and did not occur at the other depths, demonstrating low soil mobility potential. In soils incorporated with organic material, higher concentrations of oxadiazon were observed over different depths and evaluation periods.

#### TH013

##### Evaluation on the joint toxicity of Chlorpyrifos ethyl and Fenobucarb on cholinesterase activity in Climbing perch fish (*Anabas testudineus*, Bloch, 1792) from rice paddy in the Mekong Delta, Vietnam

**T.T. Nguyen Thanh**, Stockholm University / fisheries; H. Berg, Orebro University; N.H. Pham, C.V. Nguyen, Can Tho University / College of Environment and Natural Resources

**Abstract** Climbing perch (*Anabas testudineus*, Bloch, 1792), is an important food fish to local people in the Mekong Delta. Although no official statistic, the wild population of climbing perch has declined during the recent years.

Organophosphates, such as chlorpyrifos, and carbamates, such as fenobucarb, are commonly used to control a wide range of pests in rice fields. These pesticides are highly toxic to aquatic organisms due to their ability to inactivate the enzyme acetylcholinesterase. This study assesses the combined effect of chlorpyrifos and fenobucarb on brain acetylcholinesterase in climbing perch fingerlings from rice field in the Mekong Delta. After spraying the, the water concentrations of both pesticides were decreased quickly below detection levels within three days. However the inhibition of brain AChE activity continued for several more days. The result also indicates a quicker and less prolonged inhibition of brain AChE activity from the mixture than when the fish were exposed to only CPF. **Keywords:** Climbing perch, Chlorpyrifos; Fenobucarb; acetylcholinesterase

#### TH014

##### Is rice a suitable test organism in sediment-contact bioassays for the assessment of sediment toxicity?

**A. Brinke**, German Federal Institute of Hydrology; G. Reifferscheid, Biochemistry and Ecotoxicology; R. Klein, Trier University; S. Buchinger, Federal Institute of Hydrology / Department G Biochemistry Ecotoxicology; **U. Feiler**, Federal Institute of Hydrology

Rice is the staple food for 50% of human population. Most rice breeding is done in sub- and tropical regions. Today, ecotoxicological research on rice focuses on toxic compounds in contaminated paddy field soils, which are already a threat for rice farmers and consumers. Pollutants are heavy metals and arsenic (mainly geogenic, but also from anthropogenic origin) as well as organic pollutants (from pesticides, air transport, etc.). The development of suitable tools for an adequate risk assessment on rice fields is consequently highly required. Up to now, only ecotoxicological bioassays with rice focus on aquatic in vivo testing. However, sediment-contact bioassays provide a more realistic scenario for the ecosystem functions of sediments and hazards arising from bioavailable sediment-bound contaminants. They are therefore a more suitable method to display interactions between sediment and test organism. This study implies a sediment-contact bioassay for the assessment of sediment toxicity in tropical regions with the rice plant *Oryza sativa*. Rice was exposed on arsenic, cadmium, chromium and nickel spiked sediments. The classic endpoints inhibition of root and shoot elongation were evaluated as sensitive endpoints for sediment toxicity in single-substance tests on artificial sediment. Roots proved to be more sensitive than shoots, which is displayed in the determined  $EC_{50}$  [Shoots:  $EC_{50}(\text{As(III)})=24 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Cr(VI)})=373 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Cr(III)})=2032 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Ni(II)})=600 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Cd(II)})=477 \text{ mg kg}^{-1}$ ; roots:  $EC_{50}(\text{As(III)})=13 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Cr(VI)})=334 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Cr(III)})=1288 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Ni(II)})=218 \text{ mg kg}^{-1}$ ,  $EC_{50}(\text{Cd(II)})=408 \text{ mg kg}^{-1}$ ]. On natural sediments these endpoints did not prove to be enough sensitive. Observations were made concerning dose-dependent changes in root morphology which could not be assessed by classical root endpoints and are therefore implied as new toxicity endpoints. Characteristic changes were e.g. the loss or shortening of lateral roots. Rice showed sediment-bound pollutant induced changes in growth and is therefore a possible test organism for sediment-contact bioassays with higher plants. However, classic root endpoints are not sensitive on natural sediments. New endpoints for bioassays with higher plants could be qualitative endpoints but also alternative quantitative endpoints, concerning morphological changes of the root system.

#### TH015

##### Acute toxicity testing of two reference toxicants on a copepod species (Crustacea: Euterpina acutifrons) common in Qatari waters

**N. Deb**, ExxonMobil Research Qatar / Environmental; **S. Saeed**, ExxonMobil Research Qatar; **S. Bacha**, Environmental Studies Center / Technical; **E. Marquis**, A. Grimm, URS Qatar LLC

Bioassay of several reference toxicants on phytoplankton and fish embryos native to the Arabian Gulf around the Qatari peninsula have been extensively studied at the ExxonMobil Research Qatar laboratory to derive environmental quality bio-monitoring and subsequent risk evaluation of potential contaminants in the region. To obtain a more toxicologically comprehensive and ecologically representative picture of the marine ecosystem, toxicity tests were initiated on copepods. They are a major link between the primary producers and heterotrophic consumers in the marine food webs. Furthermore, marine copepods, such as *Euterpina acutifrons*, a common species in Qatari waters, have been shown to be nutritionally superior (rich in highly unsaturated fatty acids) live feed in aquaculture, an industry developing fast in Qatar. *Euterpina acutifrons* is a sexually dimorphic, pelagic, harpacticoid copepod distributed worldwide, including the Arabian Gulf. A culture of this species was successfully established in the laboratory from one gravid female obtained from the Qatari coast. The highest survival and fecundity of the species were obtained at  $22 \pm 2^\circ\text{C}$  under a 12 h light :12 h dark light regime, in cultures maintained in artificial sea water at  $40 \pm 2$  ppt salinity, and fed with a microalgal mixture of *Chaetoceros* sp. and *Synechococcus* sp. The present study evaluated in a static set-up, the acute toxicity of two reference

toxicants, sodium dodecyl sulfate (SDS) and 3, 4-dichloroaniline (DCA) on laboratory cultured *Euterpina acutifrons*. The test end point was the immobilization or reduced mobility of the copepods after 24 and 48 hours. Based on preliminary studies, different range concentrations were chosen for the two toxicants. The results show that SDS, an anionic surfactant, has a more pronounced and faster impact than DCA, on the immobilization of this species. This can be attributed to the different mechanism of action of these two toxicants. Our results suggest that low, sustained concentration of SDS can critically disrupt the marine food web by causing a decline in the copepod density within a short time. The widespread distribution, ecological importance in bottom-up and top-down control in the food web, feasibility of laboratory culturing, continuous egg production throughout the year, and short life-cycle render this copepod to be an ideal species for conducting acute and chronic life table tests for water-borne contaminants found in the Gulf waters.

#### TH016

##### **Pesticides in air in a banana production area at the Caribbean coast of Costa Rica**

L. Cordoba, Universidad Nacional / Central American Institute for Studies on Toxic Substances IRET; K. Solano, C. Ruepert, Universidad Nacional / IRET; B. van Wendel de Joode, Universidad Nacional / Central American Institute for Studies on Toxic Substances IRET

Agricultural activities in Costa Rica are characterized by intensive soil use and depend on a high input of agrochemicals due to the climate. Weekly aerial spraying of fungicides is a common procedure to control Sigatoka leaf spot at commercial banana plantations in Costa Rica, even though often situated very close to villages. Nematicides and herbicides are applied by ground application and banana bunches are protected with insecticide-treated bags. Environmental exposure to pesticides can cause ecological and human health risks. As a part of a large-research project called Infants' Environmental Health program (ISA) in which exposure and related health effects to infants are assessed in banana producing regions of Costa Rica [1], different sampling techniques were applied for evaluating environmental air concentrations of current use pesticides in the Matina county located at the Caribbean coast. Air samples were collected for six months using passive and active sampling techniques based on polyurethane foam disks (PAS-PUF) and high volume air sampler with particle collection and XAD- foam cartridges (AAS-XAD). Pesticide deposition was collected by petri dishes. The PAS-PUF samplers were located at primary schools in 12 villages of the Matina county, 10 immersed in banana plantations and 2 located at about 2 kilometers' distance. The PUF-disks were deployed for exposure periods of 27-55 days at each site and were changed 4 times between June and December 2010; a total of 51 air samples were collected. Sampling rates for the PUF-passive samplers were determined from the loss of spiked depuration compounds. The 24 hour AAS-XAD samples were taken at 4 schools, at the start and end of each PAS-PUF sampling. The insecticide chlorpyrifos was detected in all air samples with a mean of 11.2 ng/m<sup>3</sup>, for immersed schools six times higher concentrations were found as compared to referent schools. The other most frequent detected pesticides for both sampling techniques, in the gas phase, were the fungicides pyrimethanil (92%), chlorothalonil and fenpropimorph, and the nematicides cadusafos, ethopros and terbufos. The fungicides epoxiconazole, spiromoxamine and difenoconazole were detected mainly in the particulate fraction of the AAS-XAD. This behavior was confirmed by the deposition on petri dishes. Passive air samplers can be effectively used to measure average concentrations of pesticides at low levels in a tropical agricultural area. [1] ISA: www.isa.una.ac.cr

#### TH017

##### **Correlations between metallothionein, metals and fish morphometric indices indicative of environmental contamination in an anthropically impacted estuarine lagoon in Rio de Janeiro, Brazil.**

S. Nogueira, Biodiversity PostGraduate Program; T. Saint-Pierre, Puc-Rio; R.A. Hauser-Davis, Biodiversity PostGraduate Program; R.L. Zioli, UNIRIO  
Of all the environmental pollutants, metals are of particular concern due to their potential toxic effects and their ability to bioaccumulate in aquatic ecosystems. Metallothioneins (MT) are a validated biomarker for metal exposure in aquatic organisms. In fish they are usually determined in the liver, since this is the main detoxifying organ. However, recent studies indicate that metals and MT excreted in bile can also be used as biomarkers in this context. Several reports also relate metal contamination to changes in morphological parameters that describe environmental interferences in organisms, such as the Hepatosomatic Index (HSI), which identifies possible liver disorders and the Condition Factor (CF) which evaluates the general health condition of the fish. This study determined metal concentrations by ICP-MS and MT levels by UV-Vis spectrophotometry in muscle and liver of Acará specimens (n=17) (*Geophagus brasiliensis*) from an anthropically impacted estuarine lagoon in Rio de Janeiro, Brazil. Metals in bile were also determined. The CF and HSI were also calculated. Results show that Al and As accumulated preferentially in muscle. MT levels followed the trend: muscle > liver > bile. Higher MT levels in muscle are a sign of higher MT synthesis in this organ, probably due to the preferential accumulation of some metals in muscle instead of in liver or bile. These, in turn, presented lower MT concentrations. Statistically significant correlations were observed between liver MT levels and Ni in liver, while muscle MT levels correlated significantly with As and Pb in muscle. The CF was

significantly correlated with MT levels in bile and liver and with several metals in liver, while only with As in muscle. The HSI was also significantly correlated with MT levels in bile, with Al and Pb in liver and with Hg in muscle. The statistical relationships observed in this study between the CF, HSI and metals indicate that metal contamination may influence certain morphological parameters, in accordance with the literature, while the correlations between MT and metals are useful in investigating environmental contamination. MT concentrations in fish bile have corroborated with previous studies, indicating that they are adequate biomarkers for recent metal exposure, following the same trend as hepatic concentrations, and are useful as a novel application of an already established biomarker in environmental monitoring programs.

#### TH018

##### **Bioaccumulation of nickel and its biochemical and genotoxic effects on the Neotropical fish *Prochilodus lineatus***

F.F. Palermo, Universidade Estadual de Londrina; J.D. Simonato, University of Londrina / Physiological Sciences; C.B. Martinez, Universidade Estadual de Londrina / Ciencias Fisiologicas

In view of the rising global demand for Ni and the corresponding potential for increased anthropogenic inputs, it is important to develop a deeper understanding of its effects on fish. Therefore, the aim of this study was to characterize Ni bioaccumulation in different tissues and its effects on a Neotropical freshwater fish (*Prochilodus lineatus*), focusing on antioxidant defenses, lipid peroxidation, metallothionein levels and DNA damage. Juveniles of *P. lineatus* were exposed to three concentrations of nickel (Ni): 25, 250 and 2500 µg.L<sup>-1</sup> or only to water (control) for periods of 24 and 96 h. The lowest Ni concentration tested was based on the Brazilian guidelines which set as 25 µg.L<sup>-1</sup> the maximum permitted Ni concentration in inland waters. After exposure, fish were killed for the removal of gills, liver, kidney and muscle samples for Ni accumulation analysis and for the biochemical (gills and liver) and genotoxic (blood and gills cells) assays. The results showed that Ni accumulates in the organs in the following decreasing order: kidney > liver > gills > muscle and that Ni accumulation also varied according to exposure time. Metallothionein levels increased in the liver and gills after exposure to Ni, implying that the presence of Ni in these tissues could induce metallothionein synthesis. We also observed that Ni exposure affected antioxidant defenses, increasing lipid peroxidation in the liver of fish exposed to Ni for 96 h at the highest concentration tested. DNA damage increased in both blood cells and gills of fish exposed to all Ni concentrations, indicating the genotoxic potential of Ni to fish. We therefore concluded that Ni accumulates in various tissues and promotes oxidative and DNA damage in *P. lineatus* and that the maximum permitted Ni concentration in Brazilian natural freshwaters is not safe for this fish species.

#### TH019

##### **Occurrence and possible impact on the aquatic environment of drugs of abuse in a Central American country as established from sewage water analysis**

A. Causanilles; J. Sibaja, Universidad Nacional / IRET; E. Emke, KWR Watercycle Research Institute; C. Ruepert, Universidad Nacional / IRET; P. de Voogt, University of Amsterdam / IBED

Chemical analysis of waste water entering sewage treatment plants (STPs) can provide information on the use of illicit drugs in the population connected to the sewer system. In recent years several studies have been published in Europe in which the daily or weekly loads of drugs of abuse transported to municipal STPs have been determined and compared showing that a variety of illicit drugs can be found in wastewater. In addition it has been shown that several of these compounds are not removed by the treatment, resulting in actual discharges in to surface waters. The present study was conducted in Costa Rica with the aim of collecting data on occurrence of illicit drugs in wastewater and surface waters in this country and to compare these levels with known data from Europe. To that end samples from two different STPs that used completely different treatment processes were collected, together with samples from nearby surface waters. In 2012 and 2014 grab samples were collected, whereas in 2014 also seven 24h composite samples of influents from each of the two STPs were collected. The concentrations of the illicit drugs were determined by an analytical procedure that involved filtration, solid phase extraction and determination by LC-Orbitrap-MS. The results showed the presence of several illicit drugs in the influents collected, including cocaine, benzoylecgonine, THC-COOH and codeine in the µg/L range and ritalinic acid and methcathinone in the ng/L range.

#### TH020

##### **Toxic effect of detergents in organisms of different trophic levels**

A.S. Sobrino-Figueroa, Universidad Autonoma Metropolitana Iztapalapa / Hidrobiologia Laboratorio Alejandro Villalobos

In this study an evaluation of the toxicity of 2 surfactants (alkyl lauryl sulfonate (LAS) and lauryl dimethyl (hidroxetil) ammonium chloride) and 4 trademarks of detergent (Ariel, Foca, Roma and Salvo) was carried out in microalgae (*Pseudokirchneriella subcapitata*, *Monoraphidium* sp.), macrophytes (*Lemna gibba* and *Egeria densa*), cladocerans (*Daphnia magna*, *D. exilis*, *Moina macrocopa* and *Simocephalus mixtus*), ostracods (*Cypris* sp.) and fish (*Danio rerio*) due to that in our country studies with these compounds are scarce. Toxicity bioassays were carried out with duration of 48 hours for tests with cladocerans and

ostracods, and 96 hours for tests with microalgae, macrophytes and fish. The organisms were exposed to five concentrations of each of the detergents in triplicate (0.1, 1.0, 10, 50 and 100 and/or 100, 200, 400, 800 and 1000 mg L<sup>-1</sup>) plus one control, without toxic. Each test at least three times was repeated. With the data obtained lethal concentration 50 (LC<sub>50</sub>) was determined by probit method (Probit-EPA, version 1.5) and a comparison between the LC<sub>50</sub> and confidence intervals was performed to evaluate the statistical significance of the differences between the different treatments with detergents. In toxicity tests were obtained significant differences in the response of species to detergents, *P. subcapitata*, *Monoraphidium* sp., *D. exilis* and *Cypris* sp. were the most sensitive species and macrophytes *Lemna gibba* and *Egeria densa* were less sensitive to these products. The toxicity of detergents containing enzymes was superior compared with detergents not have enzymes in its formulation. Due to the wastewater treatment is limited and often sewage with high concentrations of detergents are discharged directly to aquatic systems, it is important to know the potentially adverse effects of these compounds to propose appropriate measures to reduce the risk which involves their presence in aquatic environments.

## TH021

### **Oxidative damage in gills and kidney and antioxidant defense system of traíra, *Hoplias malabaricus*, injected with crude extract of cyanobacteria, *Radiocystis fernandoi*.**

M.M. Sakuragui, Federal University of Sao Carlos / Department of Physiological Ciencias; N.E. da Silva de Souza, T. Peixoto, M.G. Paulino, D. Tavares, Federal University of Sao Carlos / Department of Physiological Sciences; A.P. Terezan, J.B. Fernandes, Universidade Federal de São Carlos / Química; A. Giani, Federal University of Minas Gerais / Department of Botanical; M.N. Fernandes, Univeridade Federal de Sao Carlos / Ciencias Fisiologicas

The microcystins (MCs) are toxins produced by cyanobacteria that may increase the free radicals and induce oxidative stress in different tissues of fish. In this context, this study evaluated the toxicity of MCs present in the crude extract of *Radiocystis fernandoi* on the gills and kidney of traíra, *Hoplias malabaricus*. Fish were separated in control group (SA30D, injection with saline 0.9%) and MC group (MC30D, intraperitoneal injected with MCs (100 µg kg<sup>-1</sup> body mass) every 72h during 30 days. After that the gills and kidney were sampled and the activity of ethoxyresorufin O-deethylase (EROD), superoxide dismutase (SOD), catalase (CAT), glutathione-S-transferase (GST), glutathione peroxidase (GPx) as well as the levels of glutathione (GSH) and lipid peroxidation (LPO) were determined. No significant changes occurred in activities of EROD, SOD and GPx and in the levels of GSH and LPO of gills. However, the activity of GST increased in the gills. In the kidney, the EROD activity and GSH levels decreased, the activities of SOD, CAT and GPx increased and the activity of GST did not change. GST catalyzes the conjugation of xenobiotics with GSH, thereby facilitating their elimination from the cell. The increased activities of GST in the gills after prolonged exposures to MC suggested biotransformation responses. The increased activities of SOD, CAT and GPx and levels of LPO in the kidney indicate that the antioxidant responses was not efficient to avoid oxidative stress in the MC group injected with crude extract of *R. fernandoi*. LPO is a good biomarker of oxidative stress in the kidney after chronic MCs contamination. Financial support: CAPES Proc. 2276/2011, CEMIG Proc. GT346 and CNPq/INCT-TA Proc. 573949/2008-5. LPO- gills, kidney

## TH023

### **Framework to establish water quality criteria for livestock in Brazil**

S. Valente-Campos, SCHOOL OF TECHNOLOGY UNICAMP / LEAL Laboratory of Ecotoxicology and Environmental Microbiology; D. SPRY, ENVIRONMENTAL CANADA; J. Palhares, Embrapa; L. Rudez, Subsecretaria de Recursos Hídricos; G.d. Umbuzeiro, FACULTY OF TECHNOLOGY -UNICAMP / LEAL

Water quality standards of the Brazilian regulations are based on international or other countries data, which differ from Brazil among exposure scenarios and public management policies. On the other hand, contradictions among quality standards in force for the same water uses and the lack of transparency with respect to establishment of these criteria can cause conflicts and inappropriate water resources management. Protocols for deriving water quality criteria for drinking water and protection of aquatic life have already been developed ([www.http://mutagen-brasil.org.br/documentos/](http://mutagen-brasil.org.br/documentos/)). However, there are some gaps regarding other uses. Cattle raising activity is the single most important contributor to Brazilian economy. Good water quality for livestock is essential to preserve animal health, to ensure the supply of safe food and food production economy. The objective of this study was to develop a framework for deriving water quality criteria for livestock in Brazil for chemicals, to obtain subsidies for public policies, contributing for the quality assurance of water for animals and humans. For full water quality criteria the requirements of Canada's protocol (CCME 1993) were adopted. This requires at least three studies on three or more mammalian species and at least two in birds. However, a major shortcoming to establish water quality criteria for livestock is the absence of toxicological data. Therefore, for provisional criteria, the number of studies usually required was decreased, but without compromising the evaluation quality. In cases where the minimum data set requirements for the derivation of full water quality criteria are not met, one study in livestock and/or nonlivestock species could be used, with the most conservative livestock body weight/ water intake ratio. If not enough data are available for an

provisional criteria. QSAR methods or other mathematical models can be used to predict the toxicity and establish water quality criteria. Acknowledgement: FAPESP (2013/16887-4)

## TH024

### **Antibiotic resistance and bacterial community changes in a gradient from sea cage aquaculture in south-central Vietnam**

M. Nitz Pettersson, Stockholm University / EMB; N. Hedberg, D. Warshan, Stockholm University / Department of Ecology Environment and Plant Sciences; M. Tedengren, Department of Ecology Environment and Plant Sciences DEEP. Antibiotics are intensively used in the Vietnamese aquaculture industry in order to prevent or treat diseases affecting the cultivated fish and lobster. The small-scale family owned farms dominating the sea cage aquaculture industry are often found close to coral reefs, providing the cages with services such as clear water and shelter from waves. Overuse of antibiotics affects the microbial community present within the coral by creating antibiotic resistant bacteria, adding a selective pressure that changes the composition of the coral associated bacteria. The coral microbial community has shown to be important for corals, serving as an immune system supporting their resilience to external pressure. In this study we investigate the resistance capacity of bacteria associated with the solitary free-living coral *Fungia fungites* sampled within the Nha Trang Bay area in south-central Vietnam. The antibiotics used in the survey are the three most commonly used in aquaculture in the area (Tetracycline, Rifampicin and Vancomycin) and the antibiotic resistance is assayed in a distance gradient with sites located at 50 m up to 2700 m away from the sea cages. The 16s rRNA gene of 40 bacteria from 8 sites along the distance gradient were isolated and sequenced. Antibiotic resistance test were performed on similar strains from *Bacillus pumilus* and *B. niabensis* found at different sites along the distance gradient. *B. pumilus* and *B. niabensis* showed antibiotic resistance at sites located up to 660 m away from sea cages when compared to the more pristine site at 2700 m. The resistance to antibiotics further showed to gradually increase from 660 m to 50 m away from the farming activities, showing that the antibiotic use does affect the coral associated bacteria found close to the sea cage aquaculture activities. This might affect the immune system function provided for the coral, which might give increased sensitivity to coral diseases. It has further been shown that antibiotics can reduce the settling success among coral larvae, indicating that the antibiotics used in aquaculture may have an impact not only the bacteria associated with corals but also on several different species and functions found within the coral reef ecosystem. The antibiotic use is one of many pressures added and must be taken in to consideration with i.e. higher nutrient levels in the water caused by the intensive feeding at the farms when investigating the coral reef resilience.

### **Environmental impact of plant protection in the Norwegian catchment Skuterud analysed with the GIS-based indicator SYNOPSIS**

J. Strassemeier, ral Research Centre for Cultivated Plants / Institute for Strategies and Technology Assessment; O.M. Eklo, M. Stenrood, Bioforsk - Norwegian Institute for Agricultural and Environmental Research; E. Solbakken, R. Lågby, Norwegian Forest and Landscape Institute

The use of pesticides in agriculture causes environmental risks that must be carefully managed. On EU level various Directives and National Action Plans have set reduction of agriculture-related pollution on the agenda. To fulfil this goal the Norwegian Project STRAPP focuses to develop instruments aiming at the implementation of the most cost-effective measures. The Skuterud catchment is part of the Norwegian agricultural environmental monitoring programme. It is located approximately 30 km southeast of Oslo. The total area of the catchment is 450 ha and main land use is agriculture with a total area of 272 ha and 51 individual farmer fields. Since 1993, the farmers have provided field specific information about farming practices. For this catchment the risk indicator model SYNOPSIS-GIS was applied considering the spatial distribution of the surveyed spray schedules together with an extended GIS based datasets on land use, slope, soil types and climate. Furthermore a database on pesticides was linked giving information on formulation, active ingredient (a.i.) content and product specific drift and run-off mitigation requirements. SYNOPSIS-GIS assesses the risk of chemical plant protection products for terrestrial and aquatic organisms. It combines use data of pesticides with their application conditions and their inherent properties. The predicted environmental concentration of a.i.'s is calculated on a daily basis for soil, surface waters and off field areas considering crop interception, spray drift, surface run-off and drainage, temperature-dependent degradation in water and soil. From the daily environmental concentrations the risk potentials are calculated as the exposure-toxicity-ratio for five reference species in aquatic systems and five species for terrestrial systems. Assessments of the aquatic risk were conducted on field level and annual basis since 2004. The calculated risks were aggregated on catchment level and risk-trends could be demonstrated. A clear decline of the risk since 2004 could not be shown. Crop specific analysis within the catchment showed that winter wheat, barley and spring wheat were at a similar risk level showing low 90<sup>th</sup> percentiles of the aquatic risk with values of 0.05 for winter wheat, 0.1 for barley, 0.03 for oats and 0.08 for spring. It is planned to include possible risk mitigation measures in the SYNOPSIS assessments in order to demonstrate the impact of the measure on catchment level.

## TH026

### **Pentachloroanisole is not a relevant proxy for pentachlorophenol in the Arctic environment**

H. Kylin, Linköping University / Department of Thematic Studies Environmental Change; H. Bouwman, North-West University / Environmental Sciences and Development

Pentachlorophenol (PCP) is currently under evaluation for inclusion in the Stockholm Convention (SC). Unfortunately, there are few data on PCP in environmental samples, largely because PCA, as an ionisable compound, cannot be included in standard analytical protocols for POPs. Often, PCP is determined after derivatization to pentachloroanisole (PCA) which can be determined together with other POPs. However, PCP is also undergoes microbial methylation to PCA in the environment, and as no other sources of PCA are known it has been assumed that PCA can be used as proxy for PCP in the environment, not least the Arctic. A further complication interpreting environmental data is that PCP and PCA, to save time, often are determined together as derivatization of PCP to PCA often is done without prior separation of PCP from the PCA native to the sample. This procedure also presupposes that PCA is a functioning proxy for PCP. Compiling data from several sampling series of pine needle samples from low latitudes to the Arctic shows that PCA does not function as proxy for PCP. While PCP concentrations as expected are highest at locations where it was still in use, PCA has a northern marine signature; the highest concentration in Europe are found along the coasts of the Norwegian and Barents' Seas with lower concentrations in continental locations at similar latitudes. Regionally, the PCA concentrations are elevated at PCP hotspots (e.g., close to chemical industries), but on a continental scale PCA concentrations at these hotspots are low in comparison with the concentrations in the far north. The PCA patterns are difficult to understand if conversion of PCP is the only source of PCA to the environment. However, an increased number of natural halogenated compounds are constantly identified. It is premature to claim that the PCA found in the environment is, at least in part, natural, but it is noteworthy that boreal forest soils seem particularly prone to produce halogenated organic compounds. The high concentrations in pine needles from the coast of the Norwegian Sea could be a consequence of a marine influence (high chloride deposition) on the boreal soil. However, other sources, neither the northern or Arctic seas themselves, nor unknown anthropogenic sources can be excluded at this time. Although we feel there is enough evidence available to include PCP in the SC, it is problematic that parts of the background for the decision is faulty.

## TH027

### **Concentrations and risks of plant protection products for biota in Finnish freshwaters**

A. Karjalainen, ECHA-European Chemicals Agency; K. Siimes, Finnish Environment Institute (SYKE); A. Aaltonen, Ramboll Analytics Oy / Niemenkatu Lahti; J. Mannio, Finnish Environment Institute SYKE / Centre for Sustainable Consumption and Production

Plant protection products (PPP) are used to maximize crop yields by protecting crop against pests, weeds and plant diseases and as growth retardants. PPPs spread to land or used to seed treatment may end up into aquatic systems. In aquatic systems they can be harmful for other biota as well because they have been originally developed as poisonous to the target biota. We used solid phase extraction coupled with mass spectrometric gas chromatography (GC/MS/MS) and ultra performance liquid chromatography (UPLC/MS/MS) to analyze the concentrations of the PPP active substances, their breakdown products and other biocides in surface water samples. We compared the concentrations to environmental quality standards (EQS) and to corresponding reference values (RV) to yield risk quotients for contamination risk assessment. Our data correspond to years 2007-2012. Plant protectants were observed in both lotic and lentic waters under the influence of agriculture. Altogether 68 various compounds were observed from the 201 analyzed ones. The most frequently found compounds were phenoxy acid herbicides. Methyl chlorophenoxy acetic acid (MCPA) was the most abundant herbicide observed but its concentrations were below the nationally set EQS during the whole observation period. Ten of the observed compounds exceeded the EQSs or RVs at least once whereas the quantification limits of seven other compounds were higher than the EQSs or RVs. Of those ten compounds four were low-dose herbicides: metsulfuron-methyl (2008), triasulfuron (2011, 2012), sulfosulfuron (2008) and thifensulfuron (2008). Two of the compounds, diuron and terbutryn (2011), originated from biocide usage. Two of the compounds, furatiokarb (2009) and malathion (2010) were used as insecticides. The origin of individual peak concentrations of highly toxic organochlorine insecticides endosulfan and endrine (2009) banned in many countries remained unclear. Our monitoring data and environmental quality comparisons revealed traces of PPPs cause no extensive harmful effects in Finnish freshwaters during our observation period. Individual peak concentrations, however, demonstrated the need for continuing monitoring. Sampling sites and intensities were sparse taking into consideration the typical complex river-lake networks of thousands of lakes in Finland.

## TH028

### **Does the discovery of a new blue mussel species in Greenland have implications for its use in monitoring programs?**

L. Bach, Aarhus University (AU), Arctic Research Centre / Department of Bioscience; J. Strand; G. Asmund, Aarhus University / Department of Bioscience

Arctic Research Centre

In Greenland, we have so far assumed that there was only one species of blue mussels, *Mytilus edulis*. A brand new study, have now shown that there actually are two species: *Mytilus edulis* and *Mytilus trossulus*. The range of the two species in Greenland is unknown. As a result we do not know whether our previous monitoring programs have been based on one, the other or possibly a mix of the two species. A new study investigates the possible impacts of this discovery on monitoring studies. We study whether there are differences in ability between the two species to accumulate contaminants incl. metals from the Greenland environment. Studies of the uptake and accumulation of metals in mussels collected elsewhere in the world show indications that there may be such a difference. \n\nGreenland has a long history of using mussels as indicator organisms for environmental impact, that include monitoring of accumulation of metals in organisms due to industrial, mining or landfill pollution. In the laboratory, mussels are examined using chemical analyzes (ICP-MS) whereupon data are evaluated to detect possible metal contamination. The two mussel species are so similar that it is almost impossible to tell the difference, and as it requires genetic analyzes to know the difference, it has not been possible to take species-specific monitoring samples. Since the species might accumulate metals differently, it is highly likely that the species-composition in a blue mussel sample taken for environmental monitoring has implications for the test results and subsequent for the advice to the environmental authorities. The results of the project do not only have importance for monitoring of local effects of for example mining industry, but also at the national as well as the Arctic and larger international levels and will further contribute significantly to strengthening the knowledge base. \n

## TH029

### **Ecotoxicological investigation of the effect of accumulation of PAH and possible impact of dispersant in resting high arctic copepod *Calanus hyperboreus***

R.D. Nørregaard, Aarhus University, DMU / DCE; K. Gustavson, Aarhus University / Department of Bioscience Arctic Environment; E.F. Møller, Aarhus University / Department of Bioscience Marine Diversity and Experimental Ecology; J. Strand; Z. Tairova, Roskilde University / Life Sciences and Chemistry; A. Mosbech, Aarhus University / Department of Bioscience Arctic Environment Due to high lipid content and a slow metabolism, there is a higher risk of bioaccumulation of oil compounds in Arctic copepods. There is also a concern that the bioavailability of oil compounds is higher when oil is dispersed with dispersants. The purpose of this project was to increase the knowledge on how the use of dispersants on an oil spill may affect the passive uptake of PAH's in resting high arctic copepods using *Calanus hyperboreus* as a model organism To evaluate this, resting high arctic *Calanus hyperboreus* was caught in Disko Bay at > 250 meters depth, November 2013, and subsequent experimental work was done at Arctic Station at Disko Island Western Greenland. *C. hyperboreus* females were incubated in phenanthrene, pyrene and benzo(a)pyrene for three days in treatments with and without oil and dispersant. Results showed that with addition of oil and dispersant to water, the accumulation of PAH was significantly reduced, due to the deposition of the PAHs in the oil phase, decreasing the available PAHs for copepod uptake, leading to a significant lower PAH accumulation in the copepods with oil and dispersant. The observed bioconcentration factors deviated from expected values. For benzo(a)pyrene this could be related to slow uptake kinetics, which has been observed in previous studies for hydrophobic compounds with log  $K_{ow}$  > 6. For pyrene and phenanthrene, active metabolism and/or sorption to the walls of the experimental containers and organic particles in the water phase could have contributed to the slow uptake. Effects of the PAHs across both treatments on the egg production were not statistically conclusive, although it is the most likely an effect of the highly variable day-to-day egg production between individual copepods. During the egg production the number of dead copepods was quantified for a mortality rate over a period of 2 months. Although there was an indication that the addition of dispersant and oil increased the mortality rate, no statistically significant effects were found.

## TH030

### **The use of common sculpins (*Myoxocephalus scorpius*) as a biomonitoring organism for biological effects around mining sites in Greenland**

R.D. Nørregaard, Aarhus University, DMU / DCE; L. Bach, Aarhus University (AU), Arctic Research Centre / Department of Bioscience; C. Sonne, Aarhus University / Department of Arctic Environment

The former mining areas Black Angel Pb-Zn mine in Maarmorilik (West Greenland) and Mestersvig Pb mine (East Greenland) have caused significant metal contamination of the marine areas of especially of Pb and Zn. In order to shed light on the present contamination and possible effects in the fiord we initiated a range of studies including studies on gill and liver morphology of common sculpins (*Myoxocephalus scorpius*). Sculpins were caught and sampled at different stations known to represent gradients of low, intermediate and high Pb concentrations. Chronic lesions were observed in liver and gills which were ascribed to concentration gradients and liver concentrations of elements. The lesions were similar to those in literature studies for both wild and laboratory exposed sculpins and other fish species. We suggest that beside exposure to mining-related elements, other environmental factors such as parasites are co-factors in the development of the observed liver and gill lesions. Therefore, sculpin liver and gill pathology is

likely to be suitable health indicators when biomonitoring gradients of mining activity effects; while a larger study is required to fully evaluate the relationships.

### TH031

#### **Plants influence the deposition of POPs to remote terrestrial ecosystems**

H. Kylin, Linköping University / Department of Thematic Studies Environmental Change; H. Bouwman, North-West University / School of Environmental Sciences and Development

“Plants” have gained interest for biomonitoring of airborne POPs as they are present in most parts of the world making sampling logistics simple. Therefore, “plants” have been used to study global distillation or orographic cold trapping. To interpret the data it is essential to understand the uptake process. However, “plants” are not a single phylogenetic entity. Thus, using “plant” data to show global or orographic distillation or deposition to remote areas is complex; different “plant” taxa take up airborne POPs by different mechanisms. A basic difference is that homoihydric vascular plants have hydrophobic surfaces, while poikilohydric mosses and lichens have hydrophilic surfaces. The volatile POPs that are present mostly in the gas phase, e.g. HCHs, show the largest discrepancies between models and measurements. In spite of different seasonal air concentration profiles of  $\alpha$ -HCH and  $\gamma$ -HCH, the seasonal accumulation patterns in pine needles are similar, indicating that the uptake patterns are governed by biological, not physical-chemical processes. The seasonality of the uptake patterns strongly follow the amount of endogenous VOCs, e.g. terpenes, in the pine needles. Calculation of POP concentrations in vascular plants should not be done on a lipid mass basis; much of the hydrophobic matter in the plants, “lipids”, will not be accounted for in the lipid determination. VOCs, e.g. will evaporate during the process, and the cutin of the cuticular membrane is a polymeric lipid that will not be extracted. The uptake of airborne HCHs in poikilohydric mosses and lichens occurs by an entirely different mechanisms than in homoihydric vascular plants; uptake in mosses and lichens is governed by their hydration state. Fully hydrated moss and lichen contains 3-5 times higher amounts of HCHs than when desiccated. Again, lipid determination is meaningless. Because of these factors, studies purporting to show global distillation or cold condensation by using “plant” data are questionable and need further clarification of biological factors involved. The temperature effect on plant biology indicates that more POPs will be deposited to terrestrial ecosystems with higher temperatures rather than the opposite. Climate change with longer vegetation periods will lead to more efficient scavenging of airborne POPs in the boreal zone.

### TH032

#### **Biomarker modulation associated with marine diesel contamination in Icelandic scallops (*Chlamys islandica*): investigating the impact of an emerging pollution in the Arctic**

P. Geraudie, Akvaplan-niva AS / Petroleum and environmental group; R. Bakke, Essex University; T. Milinkovitch, University of La Rochelle; h. thomas, The Arctic sea ice cover decline, due to ongoing climate change, will ineluctably result in the intensification of human activities in polar areas, including shipping activities, offshore oil and gas exploration, tourism and fishery. As only marine diesel has been allowed as shipping fuel by Norwegian authorities around Svalbard costs, it is important to study the impact of this fuel on Arctic ecosystems. Significant amounts of oil including marine diesel are released into the Barents Sea due to shipping accidents or chronic leakages. Chemicals associated with oil such as polyaromatic hydrocarbons have been shown to induce deleterious effects on exposed organisms and ecosystems. This study investigated for the first time the biological effects of marine diesel in Icelandic scallops (*Chlamys islandica*), a key benthic species from Arctic and subarctic ecosystems. Using a seven-day contamination protocol with three environmentally relevant concentrations of marine diesel and a control, a suite of biomarkers related to antioxidant response, neurotoxic effects, gonad maturation and lipid content was investigated.. A strong inhibition of muscular acetylthiocholine activities was observed in contaminated Icelandic scallops while a significant induction of catalase activity was observed with a concentration-dependent manner. In addition, gonad maturation was significantly inhibited in males exposed to the highest concentration of marine diesel but no effect was found in females. No impact of marine diesel exposure on lipid content was observed in Icelandic scallops. These results showed evidence of sublethal effects of marine diesel on Icelandic scallops, with a combination of oxidative stress, neurotoxic effects, and reproductive impairments suggesting a significant impact on the general biology of scallops. As marine diesel was able to affect key biological and physiological functions such as reproduction, nervous system and oxidative stress, potential adverse effects at the population levels might be expected. Overall, this study contributes to the better knowledge of physiological effects of marine diesel in marine arctic species.

### TH033

#### **Bioaccumulation and toxicity of sediment-associated Triclosan in *Tubifex tubifex*: A comparative study between temperate and subtropical sediments**

R. Windfeld, Roskilde University / ENSPAC; D.T. Salvito, Research Institute for Fragrance Materials (RIFM) / Dept of Environmental Science; H. Selck, Roskilde University / Dept Environmental Social and Spatial Change

Many of the compounds used in everyday personal care products (PCPs) are transported by waste water to the aquatic environment. Since many of these

compounds are highly hydrophobic, they will in most cases adhere to particles in the water column and settle in the sediment. Highly urbanized areas in South China, without previous waste water managements, have a high environmental concentration of PCPs such as Triclosan (TCS). Guangzhou in south China has only recently implemented waste water treatment plants, which will decrease the concentration of compounds entering the aquatic environment. However, the legacy of already embedded chemicals in the river sediment is not fully understood. We experimentally assessed bioaccumulation and biodegradation of TCS in subtropical and temperate sediment with and without *Tubifex tubifex* presence. Subtropical sediment from Guangzhou, China, and temperate sediment from Roskilde, Denmark was spiked with TCS (0-400  $\mu\text{g TCS/g dw sediment}$ ) and exposed to *T. tubifex* in a concentration-response setup. End-points included mortality and reproduction. All tests (both sediments) were executed at 17 and 28 °C to assess the importance of temperature in both regions. Results will be discussed comparing subtropical and temperate sediment results on biodegradation of PCPs by microbial degradation and macrofaunal biotransformation.

### TH034

#### **Acute, chronic and biochemical effects of chlorothalonil on *Smilisca baudinii* and *Agalychnis calidryas* tadpoles**

P. Obando, Universidad Nacional de Costa Rica; F. Mena, Universidad Nacional / Instituto Regional de Estudios en Sustancias Tóxicas; C. Ruepert, Universidad Nacional / IRET; L.E. Castillo, Universidad Nacional, Costa Rica / IRET  
Declines of amphibian populations have been a worldwide issue of concern for the scientific community during the last decades. Efforts are being carried out to elucidate factors related to those population declines. Among these factors, pathogens, climate change and environmental pollution have been suggested as possible causes. Regarding environmental pollutants, pesticides are considered a major suspect. Some of these compounds are persistent in the environment and capable of being transported long distances from their release point. In Costa Rica, some pesticides have been detected in protected areas, far from where they have been used and at sites where amphibian populations have declined. Information about toxicity of pesticides used in Costa Rican agriculture to amphibians is still scarce, mostly for native species. We ran toxicity tests with tadpoles of two Costa Rican native species: *Smilisca baudinii* and *Agalychnis calidryas*. Acute toxicity (96-hours static assay), chronic effects (growth and development) and biomarkers: Cholinesterase activity (ChE), Glutathione-S transferase activity (GST) and lipid peroxidation (LPO) were evaluated in tadpoles exposed to chlorothalonil, a fungicide intensively used in Costa Rica. High acute toxicity: 32.3 (26.3-39.7)  $\mu\text{g/L}$  to *S. Baudinii* and 26.6 (18.9-35.8)  $\mu\text{g/L}$  to *A. callidryas* was determined for this fungicide. The sensitivity of both species to chlorothalonil is even higher than what is reported in databases for other amphibian species. Induction of GST in both species and elevated LPO in *A. callidryas* were observed after exposure to sub-lethal concentrations of chlorothalonil. Chronic exposure to sub-lethal concentrations did not cause consistent effects in growth or development of tadpoles. Our results demonstrate that chlorothalonil has a high acute toxicity to native amphibian species and that low concentrations of it, can cause biochemical responses related to oxidative stress in tadpoles.

## **Challenges and Opportunities in Protecting Human and Ecosystem Health: Understanding the Fate, Transport, and Toxicity of Wastewater-borne Contaminants (P)**

### TH035

#### **A Model for Assessing the Fate of Contaminants in Constructed Wetlands**

S. Al-Marri, M.Y. Al-Sulaiti, ExxonMobil Research Qatar / Water Reuse  
Water management is a key focus area globally, and especially for of Qatar given its arid environment. As such, research to develop technologies to enhance beneficial reuse of treated industrial wastewater is recognized as a key challenge in this region. The Water Reuse Program at ExxonMobil Research Qatar developed a model in collaboration with Simon Fraser University (Canada) for predicting the environmental fate of contaminants in constructed wetlands. The objective of the model is to explore the capacity of various wetland designs to effectively and safely remove contaminants from industrial wastewaters such that the treated water can be reused for beneficial applications. This model provides a method to estimate the extent to which contaminants of various kinds can be expected to be removed from wetlands through a combination of transformation and transport processes under various environmental conditions and wetland characteristics. The model was constructed to represent steady-state conditions and is based on conservation of mass principles. The model was developed for the use of Type I and Type II chemicals. Type I chemicals include organic substances and Type II chemicals include trace metals and inorganic substances. The model combines calculations for (i) environmental distribution of contaminants in aquatic systems; (ii) uptake, translocation and biotransformation of contaminants in vegetation; (iii) bioaccumulation in aquatic biota of wetlands; and (iv) toxicity in aquatic biota. Model inputs include wetland characteristics (e.g. compartment volumes, dimensions, organic carbon content, biotic growth rates); environmental conditions (e.g. Inflow & temperature); contaminant properties (e.g. molecular weight, degradation half-lives). The model outputs include predicted concentrations in

various wetland compartments and mass balance inventory characterizing mass distribution and various loss processes. Simulations are provided for pyrene, arsenic and a naphthenic acid to illustrate application. Results indicated differences in wetlands ability to remove contaminants from wastewater. The removal efficiency of the wetlands was high for arsenic and pyrene but much lower for naphthenic acid. While field data are needed to confirm model predictions, the evaluative model presented in this study provides useful insights that can guide further studies for designing and monitoring the effectiveness of engineered wetlands for wastewater reuse purposes.

### TH036

**What are the facts of the matter with sex and gender in ecotoxicology studies?**  
**L. Parent**, Télé-université / UER Science et Technologie; **M. Boily**, Université du Québec à Montréal / Sciences biologiques; **P. Brousseau**, INRS Institut ArmandFrappier; **M. Fournier**, Institut Armand Frappier-INRS / Immunotoxicology Laboratory; **M. Fraser**, INRS Institut ArmandFrappier; **S. Ritz**, Northern Ontario School of Medicine / Medical Sciences Division; **C. Vaillancourt**, INRS Institut ArmandFrappier

The inclusion of sex and gender (*s and g*) is a significant challenge for environmental health studies. It is important to define what we mean by *s and g*, to demonstrate the added value of the data so generated when taken into account and to develop appropriate and relevant methods from an experimental point of view. But what about the environmental health studies conducted on animals in their natural environment? How ecotoxicologists define *s and g* in their studies? How to define the gender when working with wild animals or in the laboratory? Are these two elements considered and named as such? How their influences are measured? What are the reasons that make some research on a specific topic to consider them and other not? What are the funding agencies requirements in this regard? What are the effects of taking or not *s and g* into account on the results? What impacts this consideration has on the methodological approaches used? How *s and g* are or aren't integrated into the regulatory requirements in relation to bioassays, bioindicators and biomarkers. We will try to answer those questions based on an analysis of the scientific literature of the effect of endocrine disruptors found in personal care products (phthalates, triclosan, bisphenol A and polyphenol) on shellfish and fish hormonal and immune systems.

### TH037

**Artificial sunlight photolysis of the pharmaceuticals doxepin hydrochloride, gabapentin and quetiapine hemifumarate as single compounds and as a mixture**

**M. Herrmann**, Institute of Sustainable and Environmental Chemistry; **T. Reymann**, Leuphana University of Lüneburg / Institute of Sustainable and Environmental Chemistry; **O. Olsson**, Leuphana University Lüneburg; **K. Kuemmerer**, Leuphana University Lüneburg / Institute of Sustainable and Environmental Chemistry  
 The antidepressant doxepin hydrochloride (DOX), the anticonvulsant gabapentin (GAB) and the antipsychotic quetiapine hemifumarate (QUT) are widely used neurological drugs. They are frequently found in environmental compartments. Due to their high consumption and chemical stability, they are not fully eliminated by sewage treatment plants. Therefore, they are released to surface waters, like rivers, where they are exposed to sunlight irradiation. In this study the behavior of DOX, GAB and QUT was assessed undergoing simulated sunlight irradiation. Photolysis experiments in aqueous media were carried out in a 1000 mL batch immersion-type photo reactor using 800 mL of sample. For eight hours 20 mg/L of DOX, GAB, QUT and a mixture containing each active pharmaceutical ingredient (API) was exposed to constantly polychromatic light irradiation by means of a TXE 150 W xenon lamp. Primary elimination was analyzed by UV-LC-MS and the degree of mineralization by measuring *non-purgeable organic carbon (NPOC)* at specific time intervals, respectively. DOX was almost primary eliminated after two hours of irradiation. But the NPOC concentration still was only reduced by 5% after two hours and didn't change until the end of the experiment (eight hours). The stability of the NPOC concentration alludes to the formation of several phototransformation products (PTPs). Single treatment of GAB and QUT didn't lead to any change in parent compound or NPOC concentration. The mixture containing each API showed slower elimination kinetics for DOX due to competing effects. DOX was eliminated after four hours of light irradiation. The GAB and QUT concentration remained the same during the whole process. Mineralization was not observed. APIs followed different elimination kinetics. The mixture of APIs lead to slower elimination due to competitive effects. Considering that the elimination of the parent compound does not compulsory lead to mineralization, the formation of recalcitrant PTPs is possible and should to be further investigated.

### TH038

**Ozonation process efficiency of selected veterinary sulfonamides (sulfadiazine and sulfamethazine) removal. Technology risk assessment.**

**N.M. Lemańska-Malinowska**, Environmental Biotechnology Department; **Z.A. Gajda-Meisner**, Heriot-Watt University / School of Life Sciences; **V.A. Bjerkelund**, Norwegian University of Science and Technology (NTNU) / Dep of Hydraulic and Environmental Engineering  
 Sulfonamides (SAs) such a sulfamethazine (SMZ) and sulfadiazine (SDZ) are the oldest chemotherapeutic agents used for antimicrobial therapy and they still play an important role in veterinary mass treatment. Consequently, traces of these

compounds, alone or in combinations, have been repeatedly detected in the environment. Ozone has proven to be an economical option in water treatment either alone or in advanced oxidation processes in combination with hydrogen peroxide and/or UV for removal of recalcitrant compounds. The aim of this study was to compare the efficiency of selected sulphonamides oxidation by ozone in the aqueous solution which simulates the tap water. Also the acute toxicity of SMZ and SDZ before and after ozonation was conducted to investigate the potential environmental risks of these sulfonamides and their reduction products may pose. Initial concentrations of compounds used in the studies were 5 mg L<sup>-1</sup> for both SMZ and SDZ. Studies were carried out in aqueous solution, mimicking tap water, at stable conditions: pH ~7.0, temperature 18-20°C and a bicarbonates concentration of 350 mg<sub>HCO3</sub>·L<sup>-1</sup>. Ozone was applied in three different doses: 1 mg<sub>O3</sub> L<sup>-1</sup>, 3 mg<sub>O3</sub> L<sup>-1</sup> and 5 mg<sub>O3</sub> L<sup>-1</sup>. Compounds concentration was analyzed using HPLC. A ozone dose of 5 mg<sub>O3</sub> L<sup>-1</sup> was needed to achieve 100 % removal of SMZ and SDZ and that was reached within 10 seconds. Therefore this ozone concentration was selected for the toxicological tests. Assessment of SMZ and SDZ on mobility of *Daphnia magna* before and after ozonation (5 mg O<sub>3</sub> L<sup>-1</sup>) was the aim of toxicological part of this study. *Daphnia* acute toxicity tests were performed according to the OECD guideline 202 as range finding and definitive tests. The acute tests were conducted using seven different concentrations of samples (5-51% v/v) and blank control. After exposure for 24 h and 48 h the immobilization rate for individuals in each container was calculated. The 24 h and 48 h EC50 (immobilization) values were calculated using SigmaPlot® software. Samples have been diluted in 1:2 ratio in M7 medium. EC50 values for before ozonation (SMZ and SDZ) after 24 and 48 hours were EC50<sub>24</sub>=36.23 EC50<sub>48</sub>= 28.18 and EC50<sub>24</sub>=37.24 EC50<sub>48</sub>= 25.92 respectively. EC50 values for solution after ozonation (SMZ+O<sub>3</sub> and SDZ+O<sub>3</sub>) after 24 and 48 hours were EC50<sub>24</sub>=34.24 EC50<sub>48</sub>= 30.34 and EC50<sub>24</sub>= 36.23 EC50<sub>48</sub>=33.55 respectively. No significant differences in toxicity before and after ozonation was observed.

### TH039

**Source and role of OH radicals in DOM-sensitized photodegradation of bisphenol F, bisphenol S and bisphenol AF**

**A.O. Kondrakov**; **T. Glauner**, Agilent Technologies / Sales Services GmbH HewlettPackardStr Waldbronn Germany; **M. Majewsky**, Karlsruhe Institute of Technology (KIT) / Engler Bunte Institut Chair of Water Chemistry and Water Technology; **A.N. Ignatev**, Lomonosov Moscow State University  
 Public concern about the negative health effects of bisphenol A (BPA) and subsequent legislation changes caused an intensive search on BPA alternatives. Bisphenol F (BPF), bisphenol S (BPS) and bisphenol AF (BPAF) were considered as analogues replacing BPA in consumer products. As a result production of BPF, BPS and BPAF was intensified and the overall occurrence of bisphenols (BPs) in the environment increased [1]. It was shown that BPF and BPAF exhibit estrogenic activity, similar to that of BPA, whereas BPS is less harmful [2]. Photodegradation in the presence of dissolved organic matter (DOM) is an important natural BPA transformation pathway, whose rates are nearly equal to the rates of biodegradation [3]. Unfortunately, the knowledge on the kinetic rates and mechanisms of photodegradation of BPF, BPS and BPAF is scarce. In this work, DOM isolated from the boggy lake Hohloh was chosen as a natural sensitizer to investigate the photolysis of BPF, BPS and BPAF under simulated solar light. Comparison of DOM-sensitized and direct photolysis showed that BPF and BPS were photolabile, whereas BPAF was degraded in the presence of DOM only. Presence of Fe<sup>3+</sup>, NO<sub>3</sub><sup>-</sup> and HCO<sub>3</sub><sup>-</sup> at concentrations typical for surface waters did not strongly affect the photodegradation. Quenching of the reaction in the presence of isopropanol suggests the presence of OH radical (•OH) at a concentration of 10<sup>-16</sup> M. Implication of an accurate mass LC/QTOF analysis revealed formation of catechols as transformation products and suggested that hydroxylation upon •OH-attack was the primary degradation pathway. A moderate kinetic solvent isotope effect of D<sub>2</sub>O suggested that •OH generation primarily proceeded via the e<sup>-</sup> transfer mechanism and ruled out the <sup>1</sup>O<sub>2</sub> participation. **References** [1] C. Liao, F. Liu, H.-B. Moon, N. Yamashita, S. Yun, K. Kannan, Environ. Sci. & Technol. 46 (2012) 11558-11565. [2] S. Kitamura, T. Suzuki, S. Sanoh, R. Kohta, N. Jinno, K. Sugihara, S.i. Yoshihara, N. ### TH040

**UV photodegradation of trimipramine under different environmental variables and chemical nature of aqueous solution - biodegradation and LC-MSn characterization of the formed transformation products**

**N.D. Khaleel**, Leuphana Universität Lüneburg / Institute of Sustainable and Environmental Chemistry; **O. Olsson**, Leuphana University Lüneburg; **K. Kuemmerer**, Leuphana University Lüneburg / Institute of Sustainable and Environmental Chemistry  
 Trimipramine (TMP) is among widely used tricyclic antidepressant drugs throughout the world. It could cause toxic effects to humans and have a high risk of serious cardiovascular side effects; therefore it is important to study its environmental behavior. This research focuses on the effectiveness of ultraviolet (UV) radiation on the photodegradation of TMP, investigating the effect of different environmental variables (initial drug concentration, experimental temperature and solution pH) and different aqueous matrices (ultrapure, tap, surface

and wastewater) on the photodegradation process as well as on the formed photo-transformation products (PTPs). The degree of mineralization was studied by following the time course of dissolved organic carbon (DOC) during photodegradation process. Liquid chromatography coupled to ion-trap mass spectrometry (LC-MS<sup>n</sup>) was employed to monitor and identify the formed PTPs. Biodegradation testing of TMP and samples after the photodegradation process was studied using two tests from the OECD series: Closed Bottle test (CBT; OECD 301 D) and Manometric Respirometry test (MRT; OECD 301 F). Photodegradation kinetics followed first order reactions in all experiments except in wastewater matrix, which showed second order kinetics. The rate constants ranged between 0.0004 sec<sup>-1</sup> and 0.0013 sec<sup>-1</sup>. With regard to water type, TMP photodegradation rate decreased in the order: surface > tap > ultrapure > wastewater. The photodegradation process was highly dependent on the mediums' pH, especially because TMP solubility decreased by increasing pH. Photodegradation rate of TMP was increased by increasing temperature or decreasing the initial drug concentration. Comparison of the time course of TMP photodegradation by HPLC with that of the corresponding DOC values indicates that TMP was transformed to new PTPs without complete mineralization. The proposed phototransformation pathway of TMP in aqueous medium was by hydroxylation mainly. Finally, biodegradation tests revealed that neither TMP nor its PTPs were biodegradable under the studied conditions. Toxicity studies are required to be applied for the further characterization of the environmental and human risks due to the presence of TMP and its PTPs in the environment. Acknowledgements: This work was supported by the German Federal Ministry of Education and Research (Project SAUBER+ [02WRS1280A-JJ]).

#### TH041

**Photolysis of pharmaceuticals in the presence of dissolved organic matter**  
S.H. Norström, Umea University / Department of Chemistry; P.L. Andersson, Umea University / Chemistry Department

Environmental pollution by pharmaceuticals is an increasing threat to aquatic ecosystems globally. Pharmaceutical consumption is rising with the growing and ageing human population and more intensive food production, and recent studies have revealed pharmaceutical residues in a wide range of ecosystems and organisms. Environmental concentrations are often low, but pharmaceuticals acting on physiological systems are designed to have effects at low doses, and may thus remain biologically active in aquatic systems. Pharmaceuticals are removed from aquatic environments mainly through biodegradation, sorption to organic matter and photolysis. Many pharmaceutical pollutants in surface waters have already eluded the rigorous biodegradation environment of wastewater treatment plants, so sorption to organic matter and photolysis are increasingly important removal pathways in surface waters. Dissolved organic matter (DOM) may greatly impact photodegradation kinetics and pathways in two ways. Through photosensitization of DOM, the photodegradation rate of pharmaceuticals may increase indirectly, or conversely decrease through shielding if DOM acts as a filter. Our study aimed to investigate photolytically mediated degradation kinetics of a group of pharmaceuticals with large structural variation under environmentally relevant conditions. Three different matrices, two of which contained DOM (reference materials received from IHSS) in environmentally relevant concentrations and one which did not, were placed under an ultraviolet (UV) light source ( $\lambda > 300$  nm) for up to 128 h. Samples taken at various time points were analyzed via an online SPE/LC-MS/MS system to establish the amount of photodegradation. Preliminary results indicate that the DOM matrices greatly affected photodegradation pathways compared to a buffer solution. Several substances previously reported to degrade rapidly during lab-based UV-exposure did not do so. This presentation will report on half-lives of a large range of pharmaceuticals, which will be discussed in terms of their molecular structures and the IHSS provided quality data for the DOM substances.

#### TH042

**Biocides in Swedish sewage treatment plants**

M. Östman, J. Fick, E. Björn, R.H. Lindberg, M. Tysklind, Umea University / Department of Chemistry

Biocides are wide group of compounds that include substances with antimicrobial properties and they have a broad use in our society as preservatives, disinfectants etc. The concern for these substances has previously mainly been potential ecotoxicological properties. However there are several indications that these substances might promote antibiotic resistance development in bacteria. To understand the fate and occurrence of biocides are therefore crucial. To address this question, sewage water and sludge from several sewage treatment plants located in Sweden were sampled and analysed for the presence of biocides, antibiotics and metals. Various analytical techniques including, liquid chromatography tandem mass spectrometry (LC-MS/MS), gas chromatography mass spectrometry (GC-MS) and inductively coupled plasma mass spectrometry (ICP-MS) were used for quantification with labeled internal standard calibration. Extraction and clean-up procedures included such techniques as bead beater extraction, solid phase extraction (SPE) and gel permeation chromatography (GPC). The study included various selected compounds, such as quaternary ammonium compounds, parabens, triclosan, benzotriazoles, chlorhexidine, metals, antibiotics, phenols etc. Several of the compounds were found above their respective limit of quantification (LOQ). Quaternary ammonium compounds such as didecyldimethyl ammonium chloride

(DDMAC), cetrimonium bromide (CTAB) and benzalkonium chloride were found in high levels in the sludge (up to 200 ug/g d.w. sludge in some samples). Ciprofloxacin was the most common antibiotic found in the samples and the levels were comparable to previous Swedish studies. Understanding the occurrence and fate of these compounds within the sewage treatment plants are important to prevent further release into the environment. This work is part of the research program INTERACT, funded by the Swedish Research Council for Environment, Agricultural Sciences and Spatial Planning (FORMAS).

#### TH043

**HPLC-DAD Method Development and Validation for hormones estrogens in effluents**

V.d. Bianchi, UFABC / CCNH; E. de Lima, Universidade Federal do ABC / Centro de Ciências naturais e Humanas

Estrogen hormones, such as estrone, estriol, 17- $\alpha$ -ethinylestradiol and  $\beta$ -estradiol, are considered to be emergent pollutants, once they are not removed after usual sewage treatment. In addition, these substances are harmful for human and environmental health, therefore it is really important to evaluate the presence and the concentration of these pollutants in water bodies. In order to analyze these compounds, in this work a methodology with HPLC-DAD was developed and validated according to ICH Q2 R1 protocol. Two different kinds of C18 columns were applied to check which one would be better for the purpose of this work. The mobile phase was acetonitrile and acidified water pH 3.0, 50:50 in volume, flow 1.0 mL/min, injection volume 10  $\mu$ L, temperature 40°C and wavelength 281 nm. The developed method showed great results for reproducibility and repeatability (less than 3%) as well as good linearity ( $R^2 > 0.99$ ). To check a possible interference, caffeine was added to a mixture of these hormones, and all of them could be efficiently separated. Therefore, the validated method is suitable for analysis of effluent samples in a practical way. Keywords: HPLC-DAD, hormones, estrogens, effluent

**Wastewater from meat processing industry-current quality issues**

M. Vojinovic Miloradov; I. Mihajlovic; M. Milanovic, Medical Faculty, University of Novi Sad; N. Grujic Letic, Pharmacy; S. Pap, M. Brboric, University of Novi Sad Faculty of Technical Sciences; Z. Njezic, Food Institute Novi Sad, University of Novi Sad; N. Milic, University of Novi Sad, Faculty of Medicine / Department of Pharmacy

Meat industry is one of the major sources of the organic pollution in the food sector. The emission of untreated or insufficiently treated wastewater is very common in developing countries and consequently has harmful effects to the environment. According to that, the evaluation of wastewater status from meat processing industry is required. In this research samples from three representative meat companies on the territory of Serbia were collected in October 2013 and 24 physico-chemical parameters were analysed. The Standard Methods for the Examination of Water and Wastewater were applied. In all samples required limits of emission according to the national legislation for total suspended solids and phosphorus were exceeded. The biochemical and chemical oxygen demand of wastewater were 10 or even 50 times higher than the values prescribed by Regulations of the Republic of Serbia, No. 67/2011 and 48/2012. Therefore, the high occurrence of fats and oils in two samples were expected. The ammonia, important and common form of nitrogen in meat wastewater, was determined between 2.5 and 52.4 mg/L. The content of aluminium, chromium (VI) and total phenols were under the limit of detection while chlorides ranged from 110 to 220 mg/L. According to the obtained results mostly very scarce wastewater treatment are applied and wastewater with high content of blood, suspended solids, inorganic salts and nutrients is discharged directly to the public sewerage or natural recipients. The implementation of the advanced wastewater treatment plants followed by lower water consumption and frequent effluent monitoring by national authorities are of the utmost importance. Acknowledgement: This research has been financially supported by Ministry of Education, Science and Technological Development, Republic of Serbia (III46009).

**Evaluating the potential of constructed wetlands for attenuating pesticide losses from agricultural land to surface waters**

A. Ramos,

*A.M.Ramos<sup>a,\*</sup>, V.Ioannidou<sup>c</sup>; M.J.Whelehan<sup>b</sup>; R.Villa<sup>a</sup>; I.Guymer<sup>c</sup>; B. Jefferson<sup>a</sup> <sup>a</sup>Institute of Energy and Resource Technology, School of Energy, Environmental and Agrifood, Cranfield University, College Road, Cranfield, Bedfordshire, MK43 0AL, UK <sup>b</sup>a.m.amos@cranfield.ac.uk <sup>c</sup>Institute of Energy and Resource Technology, School of Energy, Environmental and Agrifood, Cranfield University, College Road, Cranfield, Bedfordshire, MK43 0AL, UK <sup>b</sup> Department of Geography, University of Leicester <sup>c</sup> University of Warwick* Some pesticides can periodically contaminate drinking water supplies at levels which create legal compliance challenges in Europe – particularly for substances which are difficult or expensive to remove using conventional water treatment technologies. A wide range of catchment management interventions have been suggested to reduce contaminant transfers to surface water abstraction points, including the construction of wetland systems on ditch and stream networks. Such wetlands could potentially reduce pesticide concentrations in water via a combination of degradation, sorption

and hydrodynamic dispersion as well as providing other benefits such as wildlife habitat enhancement. Here, we evaluate the potential of three constructed wetlands to attenuate pesticide concentrations and loads in the surface waters of a commercial farm in central England. Water samples were collected at different locations using automatic water samplers and flows were monitored continuously using hydraulic structures (V-notch weirs and flumes). Samples were analysed using LC-MS/MS for metaldehyde (2,4,6,8 – tetramethyl-1,3,5,7-tetraoxacyclo-octane), a selective molluscicide which is widely used in the UK and which is difficult to remove in typical drinking water treatment trains. The hydraulics of solute mixing were evaluated using a series of dye tracing studies conducted under different conditions. Preliminary results suggest very little attenuation of pesticide fluxes during storm events, due to short residence times. Some slow losses from the water column were observed between events when residence times were high. The nature and significance of such processes for catchment management are currently unknown but are expected to be relatively minor.

#### TH046

##### **Distribution of polybrominated diphenyl ethers (PBDEs) in an aquatic ecosystem receiving effluents from a sewage treatment plant (STP) in Tongyeong, Korea.**

H. Lee, Department of Marine Environmental Engineering; G. Kim, GYEONGSANG NATIONAL UNIVERSITY / Department of Marine Environmental Engineering

Polybrominated diphenyl ethers (PBDEs) are a group of the most prevailing brominated flame retardants (BFRs), and have been widely added into varieties of household products, including textiles, furniture, and electronic equipments. In 2009, penta-BDE and octa-BDE were listed in annexed to Stockholm Convention on new persistent organic pollutants, and thus have attracted extensive concern worldwide. In this study, influent, effluent, and sludge were collected from a sewage treatment (STP) in Tongyeong, Korea. Seawater, sediment, and oysters were also collected from a recipient bay that receives effluents discharged from the STP. These samples were then analyzed to investigate the effect of SPT effluent on distribution of PBDEs in the local aquatic ecosystem. The concentrations of total PBDEs ( $\Sigma_{15}$ PBDEs) in seawater and surface sediments were found in the range 0.33-14 ng/L and 2.2-307 ng/g dry weight, respectively. Vertical concentration of sediment cores showed  $\Sigma_{15}$ PBDEs decreased exponentially with increasing depth. The bioconcentration factor (log BCF) exhibited a parabolic relationship with octanol-water partition coefficients (log  $K_{ow}$ ) values for PBDEs. This result suggests that  $K_{ow}$  can be major factor governing bioconcentration mechanisms of PBDE congeners.

##### **HALOGENATED ORGANIC POLLUTANTS IN OGUN RIVER AT KARA ABATTOIR, NEAR BERGER, LAGOS, NIGERIA**

R. Alani, University of Lagos, Nigeria; B. ALO, UNIVERSITY OF LAGOS; F. Ukoakonam, University of Lagos Nigeria / Chemistry  
Ogun River, with the reservoir capacity of 690 million m<sup>3</sup>, is a significant river in the western part of Nigeria. This river drains loads of pollutants from most parts of the western states and empties into Lagos lagoon. Kara abattoir is one of the many abattoirs along the river's course. At Kara abattoir, Ogun River serves as a dump for all abattoir wastes, and at the same time as a source of drinking water for the animals waiting to be slaughtered. The river is equally used for domestic activities by the residents along its bank. Consumers of the milk and meat products from the abattoir could be at risk of food poisoning and health complications arising from exposure to dangerous organic pollutants. Other life forms in the total ecological community could also be at risk. Water and sediment samples were collected from Ogun River around Kara abattoir and analysed for Polychlorinated biphenyls (PCBs) and organochlorine pesticides (OCPs) using gas chromatography with electron capture detector (GC/ECD). Concentrations of PCBs in water ranged from 0.000mg/L to 0.025mg/L and from 0.012 to 0.079mg/Kg in sediments. For the OCPs, water concentration ranged from 0.007 to 0.030mg/L and from 0.015 to 1.196mg/Kg in sediments. Lindane was found to have the highest concentration in the sediment while PCB 52 had the highest concentrations in both water and sediment samples.

#### TH048

##### **Illicit drugs monitoring in the Turia River Basin**

M. Andres Costa, Universitat de Valencia / Environmental and Food Safety Research Group; V. Andreu, CIDE CSIC UV GV; Y. Pico, University of Valencia / Medicine Preventive

Until now, emerging contaminants have been found in many rivers such as Ebro, Jucar, Guadalquivir and Llobregat [1]. A recent study shows the presence of pharmaceuticals in the Turia River Basin [2]. The aim of this research was to track traditional and emergent illicit drugs in surface water in a typical Mediterranean river basin. Sampling campaign was carried out in 2 periods in 2012 and 2013. There were 22 sampling sites distributed along the river. A total of 45 metabolites and unchanged illicit drugs that belong to amphetamines, tryptamines, piperazines, pirrolidinophenone, arylcyclohexylamine, alkaloid, opioids and cannabinoids groups were monitored. These compounds were extracted from 250 mL of water by solid phase extraction and determined by liquid chromatography triple quadrupole

mass spectrometry using an electrospray ionization source in positive ionization mode. The method detection limits ranged from 0.01 to 1.54 ng L<sup>-1</sup> and the recoveries from 57 to 127 %. The monitoring of these compounds in the the Turia River Basin shows the presence of benzoylecgonine (metabolite of cocaine) in 68.2% and 18.2% at concentration up to 60.6 and 12.7 ng L<sup>-1</sup> in 2012 and 2013 sampling campaigns, respectively. Another metabolite of cocaine is ecgonine methyl ester and it was detected only in 2013 in 13.6% at a concentration up to 108.5 ng L<sup>-1</sup>. Also, methadone was monitored in 39.3% at a concentration up to 22.7 ng L<sup>-1</sup> in 2012 and in all sampling points in 2013 at a concentration up to 40.1 ng L<sup>-1</sup>. Bufotenine and 4-MeO-PCP were detected in 27.3 and 4.6 % respectively, at concentrations ranging from 3.84 to 66.8 ng L<sup>-1</sup> for bufotenine and 37.6 ng L<sup>-1</sup> for 4-MeO-PCP. In 2013 bufotenine was not detected but 4-MeO-PCP was at concentration up to 7.6 ng L<sup>-1</sup> in 4.6%. **Acknowledgements** This work has been supported by the Spanish Ministry of Economy and Competitiveness trough the project SCARCE-CDS 2009-0065, CGL 2011-29703-C02-01 and CGL 2011-29703-C02-02. ##### **Monitoring of the genotoxicity and endocrine disrupting activity of Vistula river in the vicinity of Warsaw in Poland.**

A. Zgadzaj, Medical University of Warsaw / Department of Environmental Health Sciences; A. Skrzypczak, Environmental Health Sciences; J. Giebultowicz, Medical University of Warsaw / Department of Bioanalysis and Drugs Analysis; G. Nalecz-Jawecki, Medical University of Warsaw

Monitoring of the impact of wastewater from large agglomerations on local surface water is important to understand the influence of urban areas on the environment. Evaluation of the level of mutagens and endocrine disruptors in surface water is particularly important to determine the risk of disturbances in the homeostasis of ecosystem. In this research the water samples were obtained from Vistula (the largest Polish river) in the vicinity of Warsaw, the capital of Poland. Five sampling points were located upstream and downstream from the outlet of the main Warsaw wastewater treatment plant. The samples have been collected every quarter over two years. The genotoxicity of all samples was assessed by the *umu*-test according to the ISO 13829 protocol with *Salmonella typhimurium* TA1535/pSK1002 as the test organism and by the Ames Microplate Format Mutagenicity Assay<sup>TM</sup> with five bacteria strains. Both tests were performed with and without metabolic activation. The estrogenic and androgenic agonist and antagonist activities of tested samples were evaluated by the XenoScreen XL YES/YAS assay using *Saccharomyces cerevisiae* strains with human estrogen and androgen receptors. The results of *umu*-test show significant changes in the genotoxicity of samples during the year which may be related to the water level of the Vistula river. The most genotoxic were the samples from the first sampling point situated downstream from the wastewater treatment plant. Moreover these samples were mutagenic for almost the whole duration of the experiment and the genotoxicity of the samples gradually decreased in the next downstream sampling points. The microplate version of Ames test was found to be inappropriate in case of this study because of ambiguous results. The XenoScreen XL YES/YAS assay show no estrogenic or androgenic agonistic and antagonistic activities of the water samples. This project was funded by The National Science Centre, NCN (2011/03/B/NZ7/00751).

##### **Pharmaceuticals and personal care products in the Turia River Basin**

E. Carmona, University of Valencia / Environmental and Food Safety Research Group Department of Food Chemistry and Nutrition Faculty of Pharmacy University of Valencia; A.N. Fernandes, Institute of Chemistry; V. Andreu, CIDE CSIC UV GV; Y. Pico, University of Valencia / Medicine Preventive  
The term “emerging pollutants” stands for the substances that are released in the environment for which currently no regulations are established for their environmental monitoring. Their occurrence is reported worldwide in a range of aquatic environments, such as lakes, rivers, freshwater catchments, estuaries, reservoirs and marine waters. However, there are still few studies on their occurrence, levels and distribution in River Basins from Spain. This study is aimed at contributing information on the occurrence of pharmaceuticals and personal care products in the Turia River Basin, a typical Mediterranean River heavily affected by drought. Selected contaminants include more than 40 pharmaceuticals, 5 personal care products and two illicit drugs. These substances were determined with an Agilent Technologies HPLC linked with a Triple Quad LC/MS in positive and negative ion mode testing the application of NH<sub>4</sub>F as salt in the mobile phase to improve the sensitivity. The optimal mobile phase was a gradient of 5mM Ammonium fluoride in water (mobile phase A) and 5mM Ammonium fluoride in methanol (mobile phase B) at a flow rate of 0.2mL/min with a gradient that starts with 30% of mobile phase B and increase until 95% at minute 12 and remains 13 minutes. The analytes were extracted from 250 mL of water by solid-phase extraction using Strata-X cartridges, eluted with methanol, evaporated and dissolved in 250 µL of methanol. This procedure provides acceptable recoveries

(>70%) and relative standard deviation (RSDs < 20 %) at the limits of quantification, which are in the low ppb range ensuring sensitivity enough. Some of the studied compounds were detected at low amounts in the analysed water, which establish the real environmental occurrence of these potential contaminants. Further research will be devoted to characterize their sources and source pathways as well as to define and quantify processes that determine their transport and fate through the Turia River and to identify potential ecologic effects.

#### TH051

##### **Ecotoxicological risk of the seasonal bisphenol A concentration in the Danube along Novi Sad, Serbia**

M. Milanovic, Medical Faculty, University of Novi Sad; J. Radonic, Faculty of Technical Sciences; M.M. Turk Sekulic, Department of Environmental Engineering and Occupational Safety and Health; M. Vojinovic Miloradov; I. Mihajlovic; J. Sudji, University of Novi Sad / Faculty of Medicine; N. Grujic Letic, Pharmacy; N. Milošević, University of Novi Sad / Faculty of Medicine; N. Milic, University of Novi Sad, Faculty of Medicine / Department of Pharmacy Bisphenol A (BPA), as an organic compound extensively used in daily life products, has been receiving the increasing attention due to the endocrine-modulating property to interfere with hormonal action and with the human cell functions mainly through the interaction with specific receptors. The presence of this synthetic estrogen in the environment is associated with a range of health disorders such as fertility problems, obesity, especially in children and adolescents, disrupted pancreatic  $\beta$ -cell and thyroid hormone function, cardiovascular disorders and increased carcinogenic risk. Despite its short half-life of about 0.5-5 days in the aquatic environment, the constant release into the surface water through direct discharge of municipal and industrial wastewater makes BPA a pseudo-persistent pollutant in the environment. According to all, the aim of the study was to monitor seasonal BPA concentrations and to assess the potential ecological risks during a one-year period. The surface water samples were collected in dark amber glass bottles at eight representative locations along the Danube of the Novi Sad municipality, Serbia, during autumn, winter, spring and summer under the comparable meteorological conditions at all sites for each sample at the depth of 2 m. After the preconcentration step using Bond ElutPlexa type of cartridges, the seasonal concentrations of BPA were measured by the gas chromatography-mass spectrometry. Although, BPA was only detected in two samples in winter due to the weather conditions, high frequency of the detection was observed in autumn, spring and summer at significantly high concentration levels up to 692.6 ng/L. The environmental risk assessment was evaluated by comparing the 95th percentile of the measured environmental concentration for each sampling site and the predicted no-effect concentration (0.06  $\mu$ g/L for BPA) in order to evaluate the BPA adverse effects on the Danube surface water. The calculated ratio ranged from 0.68 to 11.54 and the risk quotient was above 1 at seven locations. It can be concluded that the aquatic environment along the Danube of the point at the 1255 km, is not sufficiently protected from the adverse effects to the BPA exposure at the established water concentrations. Acknowledgement: This research has been financially supported by Ministry of Education, Science and Technological Development, Republic of Serbia (III46009) and NATO Science for Peace Project ESP.EAP.SFP 984087.

##### **Effects of non-specific binding on the biotransformation rate of hydrophobic chemicals on an in vitro metabolism assay using rat liver S9 fraction**

H.J. Lee; J. Kwon, Korea University / Division of Environmental Science and Ecological Engineering; B.I. Escher, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology Enzymatic transformation of highly hydrophobic compounds is amongst the most important factors modulating their persistence and bioaccumulation potential. It is well-known that hydrophobic chemicals strongly sorb to cellular matrices and this sorption affects their bioavailability. Physiologically-based pharmacokinetic models used for the derivation of whole-body bioaccumulation factor require the bioavailable fraction for enzymatic degradation. However, little is known about how enzyme kinetics is influenced by cellular binding or sorption. In order to elucidate effects of non-specific sorption, we measured apparent enzymatic kinetics in an in vitro assay using four hydrophobic polycyclic aromatic hydrocarbons (PAHs), phenanthrene, anthracene, pyrene and benzo[a]pyrene, as model compounds and S9 mixture isolated from rat liver as a model enzyme mixture. In addition, bovine serum albumin (BSA) was selected as non-metabolically active protein in order to investigate effects of protein binding. Rate constants were derived from measuring the depletion of parent PAHs over time. For benzo(a)pyrene, the rate constant was also calculated by measuring the formation of phase I metabolite to confirm the results from the parent depletion method. Apparent enzyme kinetics at various experimental conditions showed that it indicates that non-specifically bound compounds are also available for enzymatic degradation. Experimental data were explained best by a new model including kinetic exchanges between non-specifically sorbed form and solute bound to metabolically active sites. The results provide an important insight in the evaluation of bioaccumulation potential using PBPK modeling.

#### TH053

##### **Pesticide residues in agricultural soil of Vojvodina Province, Serbia**

S. Lazic; D. Sunjka; I. Milovanovic, University of Novi Sad Institute for Food Technologies; M. Manojlovic, S. Vukovic, University of Novi Sad Faculty of Agriculture; P. Jovanov, Institute of Food Technology in Novi Sad Modern agriculture depends to a large extent on pesticides used for control of weeds, diseases and pests, in an effort to reduce or eliminate yield losses and preserve high product quality. Their prolonged use involves the risk of their retention and accumulation in the environment, so the analysis of these compounds has become an important part of the monitoring program. The aim of this study was to evaluate the presence of pesticide residues in soil under intensive agricultural production. The survey was conducted at 34 conventional farms in Vojvodina Province, the main agricultural area in the Republic of Serbia. In total, 60 soil samples from fields with different history of farming practices were analyzed. Samples were collected from surface (0–30 cm) soil layer. Soil samples were mixed and the average samples of 500 g were formed and transferred to the laboratory. Laboratory samples of 100 g were air-dried, milled, sieved and analyzed. Extraction and clean-up procedure was carried out using modified QuEChERS method. For pesticides quantification gas chromatographic separation with MS detection (Agilent Technologies GC-MS 7890 A Series, coupled with 5975C mass selective detector and HP 5 MS column) and high performance liquid chromatography with diode array detection (Agilent HPLC 1100 system and an Agilent Zorbax C18 column) were used. The performance characteristics of the method were established by validation procedures employing assays with standard solutions, sample blanks and spiked samples. Linearity, matrix effect, accuracy, precision, limits of detection and of quantification were determined. The suitability of this method was assessed based on its performance characteristics. The obtained results indicated that all validation parameters were satisfactory and the method was applied on real soil samples. Results of the investigated soil samples showed the presence of pesticide residues from different classes - sulfonylureas, triazines and chloroacetanilides herbicides, triazoles fungicides, as well as some insecticides. This research was carried out in the framework of the IPA project cross border cooperation Serbia-Croatia and project III43005 funded by Serbian Ministry of Education, Sciences and Technological Development.

#### TH054

##### **Presence of the insecticide permethrin in indoor environment**

S. Papini, Secretaria municipal de Saúde de São Paulo / Supervisão Técnica de Saúde Jabaquara Vila Mariana; L.E. Nakagawa, Instituto Biológico / Laboratório de Toxicologia; C.M. Nascimento, A.R. Costa, R. Polatto, Instituto Biológico / Center for Research and Environmental Protection Development Pyrethroids insecticides are commonly used to control insects in residential homes in Brazil. Although pyrethroids offer lower toxicity to human and there are few reports of non-occupational poisonings, these insecticides may cause acute neurotoxic and immunotoxic effects, endocrine disruption and possible human carcinogens too. In addition, more frequent diseases such as allergies and respiratory problems are reported after application of these insecticides, especially in children and the elderly. Pyrethroids can remain for long time in indoor environment, since, unlike the ground, there is no microbial diversity to degrade the product. Therefore, the indoor residential environment has been a potential exposure for human by pyrethroids, mainly because its use has increased. In this study we evaluated the persistence of the insecticide permethrin in a house test. Permethrin is of low to moderate persistence in the soil, with half-life between 30 and 38 days, being biodegraded by wide variety of edaphic microorganisms. A commercial product of the insecticide permethrin (emulsifiable concentrate, 38.4%) was applied in aluminium foils on the floor of a house test. Soon after the application and after 14 and 28 days, the aluminium foils were collected and the insecticide was extracted using ultrasonication in acetonitrile and quantified by high performance liquid chromatography. There was no degradation the insecticide permethrin 14 and 28 days after application. One hundred percent of the applied product remained in aluminium foil during this period. The results show prolonged persistence the product in an indoor environment where the people spend most of their time, especially children and the elderly. It is important to understand the half-life of pyrethroids when applied indoors to reliable assessment of the actual risk of exposure. Support FAPESP 2013/17822-3

#### TH055

##### **Seasonal Occurrence, Distribution and Ecological Risk Assessment of Multiple Classes of UV Filters in Marine Sediments**

T.M. Mei Po Mirabelle, H. Leung, B.K. Kwan, K. Ng, City University of Hong Kong / Biology and Chemistry; N. Yamashita, National Institute of Advanced Industrial Science / Emtech; S. Taniyasu, AIST / Institute for Environmental Mgmt Technology; P. Lam, City University of Hong Kong / Department of Biology & Chemistry; M.B. Murphy, University of Hong Kong / Dept of Biology Chemistry Organic ultraviolet (UV) filters are common ingredients in personal care products such as sunscreens and cosmetics to protect human skin against sunburn by absorbing UV radiation; they can also be used to improve product stability. These compounds can enter the aquatic environment through recreational activities and via wastewater treatment plants. The increasing incorporation of organic UV filters into products has raised concern about their potential environmental impacts, but the occurrence and risks of these compounds in the marine environment are not well understood. This study aims to (1) develop quantitative analytical methods for the simultaneous multiclass determination of 11 commonly-used UV filters (4-MBC,

BMDM, BP-1, BP-3, BP-8, EHS, HMS, IAMC, OMC, OC and OD-PADA) in sediment, (2) determine their occurrence and distribution in samples collected in Hong Kong and in Tokyo Bay, and (3) conduct a preliminary environmental risk assessment of these compounds in the marine environment. In Hong Kong, seven of the 11 target UV filters were detected in the samples, with median concentrations ranging from < LOD to 21 ng/g dw. Generally, the detection frequencies of UV filters were higher in the wet season than in the dry season, and BMDM, BP-1, BP-8 and EHMC showed detection frequencies >50%. Composition profiles in Hong Kong and Tokyo Bay showed that BMDM, EHMC and ODPABA were the predominant compounds in sediment samples accounting for more than 60% of the total UV filter occurrence, while all of the benzophenone derivatives accounted for < 35%, likely due to their relatively lower estimated soil organic carbon partition coefficients (log  $K_{oc}$ ) values (benzophenone-derivatives: 2.8-3.8; other detectable compounds: 4.4-6.8). Probabilistic ecological risk assessment showed that the likelihood of EHMC causing toxic effects on reproduction in snails was over 84% and 32% using toxicity thresholds based on data for two species, suggesting potential risks of UV filters to benthic organisms as well as possible wider effects on the marine food web.

#### TH056

##### **Nutrient, metal, microbial and pharmaceutical runoff losses following treated sewage sludge application to an Irish grassland soil: a rainfall simulation study**

D.P. Peyton, Teagasc Environment Research Centre / Environmental Research; M.G. Healy, NUI Galway / Civil Engineering Co Galway; M. Danaher, H. Cantwell, Teagasc the Irish Agriculture and Food Development Authority / Food Research Centre Ashtown Co Dublin; G.T. Fleming, NUI Galway / Microbiology Co Galway; J. Grant, Teagasc the Irish Agriculture and Food Development Authority / Food Research Centre Ashtown Co Dublin; D. Wall, Teagasc the Irish Agriculture and Food Development Authority / Environment Research Centre Johnstown Castle Co Wexford; L. Morrison, NUI Galway / Earth and Ocean Sciences Co Galway; M. Cormican, NUI Galway / School of Medicine Co Galway; O. Fenton, Teagasc the Irish Agriculture and Food Development Authority / Environment Research Centre Johnstown Castle Co Wexford

Treated sewage sludge ("biosolids") may be applied to agricultural land as an organic fertiliser, as it offers an excellent source of nutrients and metals required for plant and crop growth. Due to the increasing awareness among the public and scientific community regarding the possible risks to the environment and human health, the application of biosolids to land as a fertilizer has come under increased scrutiny in recent times. While there are many benefits accruing from the land application of biosolids, any nutrient recovery must be considered against possible adverse impacts associated with their reuse. The aim of this study was to quantify the loss of nutrients (phosphorus and nitrogen), metals (copper, nickel, lead, zinc, cadmium, chromium, aluminium, iron and manganese), faecal and total coliforms, and emerging pharmaceuticals (triclosan and triclocarbon), under controlled, in-field conditions during and after successive rainfall simulation events. Four types of biosolids (two types of anaerobically digested biosolids, one sourced from the UK and the other from Ireland; lime stabilised and thermally dried biosolids) were surface applied to replicated (at n=5) hydraulically isolated micro-plots, each 0.9 m long x 0.4 m wide. Prior to application, the biosolids and plots were fully characterised for nutrient, metal, microbiological and pharmaceutical parameters of interest. Rainfall with an intensity of 11 mm hr<sup>-1</sup> was applied to each plot using a portable multi-drop rainfall simulator, over three successive 30 min rainfall events at three time intervals of 24, 48 and 360 hr from the time of application (all plots were covered between rainfall events using rain-out shelters). Runoff water samples were collected and fully characterised. The flow-weighted mean concentrations (FWMC) measured in the surface runoff indicated that nutrient losses, while high, were similar to other organic wastes, metal concentrations were well below their respective drinking water limits, and faecal coliforms did not persist as long, and were lower than untreated cattle slurry. The FWMC measured in this study represented a 'worst case' scenario for potential losses, but further buffering is possible further down the transfer continuum. Pharmaceutical testing of surface runoff is currently on-going and may be decisive in determining whether biosolids may be safely applied to land. **Keywords:** Biosolids; surface runoff, contaminants, rainfall simulator

#### TH057

##### **Assessment of the vermicomposting process applied to sewage sludge by monitoring of the compost quality and immune responses of earthworms**

A.B. Rorat, Institute of Environmental Engineering, CUT, Poland; H. SULEIMAN, PRES Lille University North of France / Czestochowa University of Technology / LGCgE University of Lille 1 / Institute of Environmental Engineering; M. KACPRZAK, Czestochowa University of Technology / Institute of Environmental Engineering; B. PLYTYCZ, Jagiellonian University / Institute of Zoology; F. VANDENBULCKE, LGCgE, Université de Lille 1 / LGCgE EA Univ Lille Fonctionnement des Ecosystèmes Terrestres Anthropisés Cité Scientifique SN Rdc F Villeneuve d'Ascq France

*Eisenia andrei*, *Eisenia fetida* and *Dendrobaena veneta* are test annelid species, that play a major role in many ecotoxicological, biological and genetic studies. These species showed the ability to inhabit polluted areas and many studies indicated their ability to accumulate pollutants, such as Metallic Trace Elements (MTEs).

They also change the bioavailability of metals for plants, which may constitute a risk but also a great interest when employing these capacities in the treatment of the sewage sludge through vermicomposting process. This eco-technique is a non-expensive and rapid method of biodegradation of organic wastes, inter alia sewage sludge, commonly used in developing countries. The quality of the product can be assessed using agronomic parameters, while immune and defense parameters can be measured as stress biomarkers. Aims of this work were: 1) to segregate worms coming from mixed colonies using DNA barcoding and fluorophores fingerprinting, 2) to assess the influence of pollutants on immune system (gene expression and immunocyte sub-populations, 3) to assess the quality of the product by measuring physical and chemical parameters. Earthworms were segregated into three separated groups basing on DNA barcoding and selected fluorophores were tested as non-invasively retrieved biomarkers allowing distinction between morphologically similar composting earthworm species. Riboflavin, coelomocytes (amoebocytes/eleocytes) composition and particular gene expression levels were selected as biomarkers of stress useful in biomonitoring of vermicomposting process. Applied technique has led to valorization of sewage sludge, by changing their physical and chemical properties and obtained product can be considered for future applications as fertilizer.

#### TH058

##### **Bio-physico-chemical behavior of photocrosslinked silicone acrylates**

S. OUALI, Y. LOUIS, P. GERMAIN, R. GOURDON, V. DESJARDIN, INSA de Lyon / Laboratory of Civil and Environmental Engineering

Photocrosslinked silicone acrylates are used for a broad variety of applications, such as photocurable coatings, printing inks and adhesives, which all require the use of a photoinitiator (PI). As an UV PI, Darocur 1173 (2-Hydroxy-2-methyl-1-phenyl-propan-1-one) is widely available and well investigated. However, the environmental issue is the possible dispersion of chemicals both during the use and at the end of life of the product. Although the PI represents only a minor part of the formulation, this emission process is closely related to the migration of these molecules. In fact, the most severe requirements regarding migration properties are imposed only on UV curable printing inks for food packaging applications and for pharmaceutical products. Regarding the end of life, the behavior of silicone in wastewater treatment plants and landfills has been poorly studied and their possible environmental impact is not known. Furthermore, to our knowledge no studies have been published on the behavior and fate of photocrosslinked silicone acrylates. Thus, the aim of this work was firstly to synthesize photocrosslinked silicone acrylates elastomers, then to assess the release of PI by leaching test. Finally to assess the biodegradation process of elastomers and PI over time under aerobic and anaerobic controlled conditions. Laboratory experiments were conducted in order to simulate the end of life conditions for silicone acrylates, whether in wastewater treatment plants or in landfills. Both physico-chemical and molecular biological techniques (molecular fingerprint TTGE and qPCR) were used to study the effect of elastomers on bacterial and fungal communities under the tested conditions. The results show that the PI is a very mobile compound, almost all of the amount used to synthesize the elastomers was released after 10 days of experiments. Silicone elastomers and the PI are not biodegraded in anaerobic conditions but they inhibit the biodegradation process. Under aerobic conditions the PI was totally biodegraded and used as a carbon source contrary to the silicone elastomer. This study provide information that contribute to the assessment of their possible fate and environmental impacts during their use and at their end of life. This methodology may be used to evaluate alternative photoinitiators in the objective to substitute the potentially toxic photoinitiators such as Darocur 1173 by more environmentally friendly formulations.

## **Contaminants of Emerging Concern in Food Webs: Impacts on Non-Target Organisms (P)**

#### TH059

##### **Accumulation and depuration of per- and polyfluorinated compounds from bottom sediment by a freshwater amphipod (*Gammarus* spp.): assessment of exposure routes, accumulation and depuration kinetics**

D. Bertin, Irstea / Water MALY Ecotoxicology Laboratory; M.P. Babut, Irstea / Water; G. Munoz, LPTCEPOC 5805 CNRS / UMR EPOC LPTC; P. Labadie, H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC

Long chain perfluoroalkyl acids, sulfonates and a few precursors have been found in water, sediment, benthic invertebrates (oligochaetes, chironomids, gammarids etc.) and fish from the Rhone River downstream of an industrial platform using an array of fluorotelomers and other fluorinated compounds. Among the investigated species, gammarids appear as one of the most contaminated, with concentrations similar or above those displayed by oligochaetes. These taxa have rather different life traits: whereas oligochaetes spend their whole life in sediment and feed on highly decomposed organic matter, gammarids are rather pelagic and detritivorous shredders. In order to better understand how gammarids are contaminated, the objectives of the study were (i) to identify the exposure routes for *Gammarus* spp. and (ii) to describe the accumulation and depuration kinetics in this taxon. Contaminated field sediment was collected in the Rhone River, sieved and homogenized, and disposed in aquaria. *Gammarus* spp. were collected at a

reference site, acclimated in the laboratory, and added to the aquaria, along with alder leaves. After 21 days of exposure, the gammarids were transferred to clean (water-only) aquaria and allowed to depurate for 21 days. An array of about 25 per- and polyfluorinated compounds (PFASs) were measured at different exposure and depuration times. Although the steady state was not achieved at the end of the exposure period, it was possible to determine uptake rates ( $k_u$ ). Depuration rates ( $k_e$ ) were also determined, and appear to be dependent on the perfluoroalkyl chain length. Overall this experiment allowed drawing a tentative conceptual model of PFASs transfer from sediment to leaves and gammarids in the aquaria, suggesting an important role of biofilms at the leaves' surface. Nevertheless, the gammarids sampled in the field at the site where sediments were collected for the experiments were much more contaminated than those exposed in the laboratory, suggesting that other exposure routes might be involved.

#### TH060

##### **Bioaccumulation of perfluoroalkyl compounds by benthic invertebrates and fish downstream of an industrial platform in the Rhone River (France)**

M.P. Babut, Irstea / Water; P. Labadie, University of Bordeaux / UMR EPOC Equipe LPTC; D. Bertin, Irstea / Water MALY Ecotoxicology Laboratory; G. Munoz, LPTCEPOC 5805 CNRS / UMR EPOC LPTC; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC

Following a screening study at the Rhone watershed scale addressing fish contamination in 2009-2010, a research focusing on the trophic networks of three cyprinid fish species (*Barbus barbus*, *Gobio gobio*, *Rutilus rutilus*) is being implemented since 2011 in the Rhone River, downstream of major per- and polyfluoroalkyl (PFASs) industrial sources. The study aims to describe the contamination pattern and its variations through the respective food-webs, and identify environmental and biological factors, as well as chemicals' properties, contributing to these variations. Surface sediment, benthic invertebrates (12 taxa) and fish (47 individuals in total) were collected between October 2011 and June 2013, prepared and analyzed for PFASs,  $d^{13}C$ , and  $d^{15}N$ . Stomach contents were also characterized, whenever possible. The biota to sediment accumulation factors (BSAFs) for C7 to C11 perfluorinated carboxylic derivatives and C8 perfluorinated sulfonates were determined on the basis of invertebrates contamination data. Fish contamination was influenced by PFASs characteristics, fish feeding behavior, and might be also influenced by their physiology. In the case of barbel (*B. barbus*), for some PFASs young fish were significantly more contaminated than adult ones, while for other compounds adults were more contaminated, though not significantly except for PFTeDA (perfluorotetradecanoic acid). Biomagnification factors (BMFs) were determined for two pairs of predator-prey, namely gudgeon (*G. gobio*) - chironomids, and barbel - gammarids. PFNA (perfluorononanoic acid), PFUnDA (perfluoroundecanoic acid), PFTTrDA (perfluorotridecanoic acid), PFOS (perfluorooctane sulfonate) and FOSA (Perfluorooctane sulfonamide) BMFs were clearly above 1 for gudgeons, much higher than for barbels, because concentrations in chironomids were lower than in gammarids. These BMFs estimates were based on concentrations measured in fish dorsal muscles, leading to an overestimation of BMF values. This would not change the conclusion for gudgeon BMFs; conversely for PFASs having less than 11 perfluorinated carbons the biomagnification in barbels appears more uncertain. Trophic magnification factors for both trophic networks will also be presented.

#### TH061

##### **ASSESSING HNS CONTAMINATION IN NW PORTUGUESE ESTUARIES: CHEMICAL LEVELS AND BIOMARKER RESPONSES IN PLATICHTHYS FLESUS**

A. Rocha; C. Teixeira, CIIMAR; C. R Almeida, CIIMAR Interdisciplinary Centre of Marine and Environmental Research; M. P Basto, CIIMAR CIMAR and Sciences Faculty of University of Porto; M. Ferreira, CIIMAR Interdisciplinary Centre of Marine and Environmental Research; L. Guimaraes, CIIMAR University of Porto / METOX Coastal and Marine Environmental Toxicology; M. Reis-Henriques, CIIMAR Interdisciplinary Centre of Marine and Environmental Research

The maritime transportation of hazardous and noxious substances (HNS) has increased over the last decades. The substances can be more toxic than oils and are often more hazardous due to their different physical and chemical properties. Thus, the increased awareness and concern focused on understanding their environmental fate and toxicological effects. The aim of this study was to increase knowledge on contamination by HNS in NW Portuguese estuaries of Minho and Douro rivers. For that, HNS levels were determined in water, sediments and tissues of the flounder (*Platichthys flesus*) and biomarker responses were evaluated in the fish liver. Samples were collected in the spring of 2014. Twenty five HNS, including chloroform, toluene, tetrachloroethylene, ethylbenzene and xylene, were measured in water, sediments and in flounder's tissue using solid-phase micro-extraction and gas chromatography with ion trap mass spectrometric detection. Metals and PAHs were also analysed as the presence of both contaminants has been previously reported in sediments of both estuaries. Several biomarkers were evaluated, namely, ethoxyresorufin-O-deethylase (EROD), glutathione-S-transferase (GST), catalase (CAT), glutathione reductase (GR), glutathione peroxidase (GPx) and superoxide dismutase (SOD) activities, lipid peroxidation (LPO) and oxidation of proteins (PCO). The obtained results were compared with previously reported data. In flounder of both estuaries, a considerable decrease in the activity of antioxidant

enzymes and the levels of lipid peroxidation was registered, in comparison with data from previous years, suggesting amelioration of habitat's environmental conditions. Correlations between biomarkers data and HNS levels provided important information on baseline situation of the study area and potential biological effects of HNS on this sentinel species. **Keywords:** HNS, flounder, biomonitoring, ecological risk assessment **Acknowledgments:** This work was funded by the Project ECORISK (reference NORTE-07-0124FEDER-000055) within the SR&TD Integrated Program MARVALOR - Building research and innovation capacity for improved management and valorization of marine resources, supported by the Programa Operacional Regional do Norte (ON.2 - O Novo Norte) and by the European Regional Development Fund; and by the Portuguese Foundation for Science and Technology (FCT) through the project PTDC / AAG-MAA/2405/2012, the COMPETE program FCOMP-01-0124-FEDER-027808 and PEst-C/MAR/LA0015/2013.

#### TH062

##### **HNS CONTAMINATION IN THE NW PORTUGUESE COAST: BACKGROUND CHEMICAL AND BIOMARKER LEVELS**

C. Teixeira, CIIMAR; A.C. Rocha, CIIMAR University of Porto; M. Ferreira, CIIMAR Interdisciplinary Centre of Marine and Environmental Research; L. Guimaraes, CIIMAR University of Porto / METOX Coastal and Marine Environmental Toxicology; M.A. Reis-Henriques, CIIMAR University of Porto; M.C. Basto, CIIMAR and Faculdade de Ciências da Universidade do Porto; C.R. Almeida, CIIMAR University of Porto

The accidents during maritime transport resulting in oil and hazardous and noxious substances (HNS) spills are a major concern at global scale. Assessment of fate and potential associated impacts of HNS poses additional challenges in that they may have a range of possible pathways or fates once released into the marine environment. The ECORISK project aims to assess the present situation of water, sediments and biota contamination by HNS in NW Portuguese coastal ecosystems in order to make an ecological risk assessment of these contaminants. Twenty five HNS were screened in water, sediments and mussels (*Mytilus* sp.) collected along the NW Portuguese coast. Samples were collected in spring of 2014 in six marine beaches. HNS were measured using solid-phase micro-extraction and gas chromatography with ion trap mass spectrometric detection. Additionally, biomarkers of exposure to contaminants (glutathione-S-transferase, catalase, glutathione reductase, glutathione peroxidase and superoxide dismutase activities; and levels of lipid peroxidation and oxidation of proteins) were evaluated in mussel's digestive gland. Toluene and tetrachloroethylene were the compounds detected in higher concentrations in water and sediment samples, respectively. Significant differences in biomarker levels were observed between the sampling sites. Comparing to previous data, there was a significant decrease in the activity of antioxidant enzymes and in the levels of lipid peroxidation in mussel's digestive gland. Possible relations of biological data with contaminants' levels in water, sediment and mussel tissues will provide important information regarding the baseline situation of the study area and potential biological effects, and will be further discussed in this communication. **Acknowledgments:** This work was funded by the Project ECORISK (reference NORTE-07-0124FEDER-000055) within the SR&TD Integrated Program MARVALOR - Building research and innovation capacity for improved management and valorization of marine resources, supported by the Programa Operacional Regional do Norte (ON.2 - O Novo Norte) and by the European Regional Development Fund.

#### TH063

##### **Potential of carbamazepine as inducer/inhibitor for pesticide toxicity**

J. Jeon, Changwon National University / Environmental Engineering; N. Park, Changwon National University / Department of Environmental Engineering; H. Jang, Changwon National University; A. Rösch, Eawag / Environmental Chemistry; J. Ra, GIST / Environmental Science and Engineering; J. Hollender, Eawag / Environmental Chemistry

A biologically degradable compound can be transformed by various kinds of enzymes whereas an enzyme species can metabolize diverse chemical moieties. Considering biota is exposed to multiple substances which are transformed enzymatically, substances can interfere with others' transformation pathways or kinetics (i.e. toxicokinetics). Thus, enzyme-multiple substances interactions should be investigated to extend our understanding of chemical effects by such environmentally relevant exposure (i.e., mixture toxicity). Carbamazepine is known as a substrate of cytochrome P450s (e.g., 3A4, 1A2), as well as an inducer (e.g., of 2B6) but also inhibitor (e.g., of 2C19). These P450s are also involved in transformations of pesticides such as diazinon, azoxystrobin, and fipronil whose transformation is critical for bioactivation or detoxification. For exploring interaction of enzymes with multiple compounds, an in-vitro enzyme incubation setup using trout liver homogenate was established. In the present study, in-vitro transformation products of carbamazepine and pesticides formed in the homogenate were identified for the single compounds with suspect/non-target screening method using high resolution mass spectrometry. Then, the enzyme incubations with binary chemical mixtures were conducted to assess the potential of carbamazepine as an inducer/inhibitor of P450 (so as to regulate bioactivation/detoxification process).

#### TH064

##### **Interactive effects of salinity and an antidepressant on *Carcinus maenas***

A.P. Rodrigues, CIIMAR / METOX Coastal and Marine Environmental Toxicology; L. Santos, Faculty of Engineering - University of Porto / Chemical Engineering; I.O. Abreu, C. Monteiro, CIIMAR Interdisciplinary Centre of Marine and Environmental Research; M.T. Oliva-Teles, C. Delerue-Matos, REQUIMTE; S.R. Mesquita, Center of Marine and Environmental Research CIIMAR / METOX Coastal and Marine Environmental Toxicology; L. Guimaraes, CIIMAR University of Porto / METOX Coastal and Marine Environmental Toxicology

Often estuarine organisms suffer the simultaneous impact of man-made chemicals and natural stressors. Although, this usually results in occurrence of synergistic and/or antagonistic interactions, limited information is yet available on such combined effects have been described. This study, thus, investigated the combined effects of strontine (SERT) and salinity on bioaccumulation and biomarkers of neurotransmission, antioxidant defences, and oxidative damage of *Carcinus maenas*. The biomarkers employed were related to the mode of action (MoA) of SERT and to cellular processes influenced by salinity stress, and provided a link between physiological changes and possible ecological consequences. These biomarkers are widely recognised as useful early-warning tools to evaluate environmental contamination. The effects of two environmentally realistic concentrations of SERT were assessed at two salinity levels: brackish water (BW) and seawater (SW). Significant accumulation of SERT was only found in crabs exposed in SW. Synergism and antagonism were identified for biomarkers of cholinergic neurotransmission, antioxidant defences, and oxidative damage. The biomarkers tested appear to be more sensitive than common regulatory endpoints like survival, growth or reproduction in daphnids. Different interactions (synergism and antagonism) between salinity and SERT were found. Differences were also observed for interactions involving low and high SERT concentrations. The results support the urgent need for multiple stressors evaluations, involving emerging contaminants of concern and natural stressors associated to global climate changes, to improve ecological risk assessment for these chemicals. This work was funded by Project ECORISK (reference NORTE-07-0124FEDER-000055) within the SR&TD Integrated Program MARVALOR - Building research and innovation capacity for improved management and valorisation of marine resources, supported by the Programa Operacional Regional do Norte (ON.2 – O Novo Norte) and by the European Regional Development Fund; and by the Portuguese Foundation for Science and Technology (FCT) through project PEst-C/MAR/LA0015/2013.

#### TH065

##### **Effluent from an NSAID-manufacturing plant in Mexico induces genotoxicity on *Cyprinus carpio***

L.M. Gomez-Olivan, Universidad Autónoma del Estado de México, Fac. de / Facultad de Química; N. SanJuan-Reyes, O. Dublán-García, Universidad Autonoma del Estado de Mexico / Facultad de Química; M. Galar-Martinez, Laboratory of Aquatic Toxicology Department of Pharmacy; S. Garcia-Medina, National School of Biological Sciences, IPN. / Laboratory of Aquatic Toxicology, Department of Pharmacy.; H. Islas-Flores, Instituto Politecnico Nacional / Escuela Nacional de Ciencias Biológicas

The pharmaceutical industry generates large quantities of wastewater varying in characteristics and concentration as a function of the manufacturing process used and the year season. These effluents originate mainly as a result of machinery and, in addition to residues of the pharmaceutical products manufactured (as nonsteroidal antiinflammatory), also contain other kinds of compounds used in the cleaning process, including solvents (ethanol) and detergents such as sodium dodecylbenzene sulfonate (SDBS). There are some evidence that these products generates reactive oxygen species, causing lipid, protein, and deoxyribonucleic acid damages, by the mechanism of oxidative stress. The aim of this study is to evaluate the genotoxicity induced by an effluent from an NSAID-manufacturing plant in Mexico on *Cyprinus carpio*. Initially, industrial effluent was sampled and obtention and acclimation of *Cyprinus carpio* was conducted. The median lethal concentration (LC<sub>50</sub>) and subsequently the lowest observed adverse effect level (LOAEL) were determined. Sublethal study of the organisms (genotoxicity test) was realized using LOAEL. Exposure times were 12, 24, 48, 72 and 96 h. The damage was evaluated using the comet (Tice *et al.*, 2000) and micronucleus assay (Albertini *et al.*, 2000; Lindberg *et al.*, 2007). The LC<sub>50</sub> obtained was of 1.173 %. Results shows a significant increase with respect to the control group ( $p < 0.05$ ) after 24 h exposure in the comet and micronucleus assay. In conclusion this industrial effluent induces genotoxicity on *Cyprinus carpio*.

#### TH066

##### **Evaluation of toxicity induced by hospital wastewater effluent on *Cyprinus carpio***

L.M. Gomez-Olivan, Universidad Autónoma del Estado de México, Fac. de / Facultad de Química; N. Neri-Cruz, O. Dublán-García, Universidad Autonoma del Estado de Mexico / Facultad de Química; M. Galar-Martinez, Laboratory of Aquatic Toxicology Department of Pharmacy; S. Garcia-Medina, National School of Biological Sciences, IPN. / Laboratory of Aquatic Toxicology, Department of Pharmacy.; H. Islas-Flores, Instituto Politecnico Nacional / Escuela Nacional de Ciencias Biológicas

The very wide range of activities performed by hospitals (care, diagnostics, hygiene, maintenance, research) lead them to use a great variety of potentially ecotoxic substances, such as surfactants, disinfectants, and pharmaceuticals. The

contact of these pollutants with aquatic ecosystems leads to a risk directly related to the existence of hazardous substances that could have potential negative effects on biological balance of natural environments. This study aimed to determine oxidative stress induced on the common carp *Cyprinus carpio* by effluent from a hospital in Mexico. The median lethal concentration (LC<sub>50</sub>) and subsequently the lowest observed adverse effect level (LOAEL) were determined. Carp were exposed to the latter value (0.5%) for different exposure periods (24, 48, 72 and 96 h) and the following biomarkers were evaluated in gill, brain, liver and blood: hydroperoxide content (HPC), malondialdehyde content (MDA), protein carbonyl content (PCC), and the activity of the superoxidant enzymes superoxide dismutase (SOD) and catalase (CAT). Statistically significant increases with respect to the control group ( $P < 0.05$ ) were observed in HPC, LPX and PCC particularly in gill, liver and brain of effluent-exposed specimens. SOD and CAT activity in liver and brain also increased with respect to the control group. This particular hospital effluent is therefore concluded to induce oxidative stress on *C. carpio*, this damage being most evident in gill, liver and brain.

#### TH067

##### **A survey of benthic sediment contaminants in reaches of the Columbia River Estuary based on channel sedimentation characteristics**

T.D. Counihan, United States Geological Survey; I.R. Waite, US Geological Survey; E.B. Nilsen, US Geological Survey / ORWSC; J. Hardiman, USGS; E. Elias, United States Geological Survey; G. Gelfenbaum, United States Geological Survey

While previous studies have documented contaminants in fish, sediments, water, and wildlife, few specifics are known about the spatial distribution of contaminants in the Columbia River Estuary (CRE). Our study goal was to characterize sediment contaminant detections and concentrations in reaches of the CRE that were concurrently being sampled to assess contaminants in water, invertebrates, fish, and osprey (*Pandion haliaetus*) eggs. Our objectives were to develop a survey design based on sedimentation characteristics and then assess whether sediment grain size, total organic carbon (TOC), and contaminant concentrations and detections varied between areas with different sedimentation characteristics. We used a sediment transport model to predict sedimentation characteristics of three 16 km river reaches in the CRE. We then compartmentalized the modeled change in bed mass after a two week simulation to define sampling strata (strata) with depositional, stable, or erosional conditions. We collected and analyzed bottom sediments to assess whether substrate composition, organic matter composition, and contaminant concentrations and detections varied among strata within and between the reaches. We observed differences in grain size fractions between strata within and between reaches. We found that the fine sediment fraction was positively correlated with TOC. Contaminant concentrations were statistically different between depositional vs. erosional strata for the industrial compounds, personal care products and polycyclic aromatic hydrocarbons class (Indus-PCP-PAH). We also observed significant differences between strata in the number of detections of Indus-PCP-PAH (depositional vs. erosional; stable vs. erosional) and for the flame retardants, polychlorinated biphenyls, and pesticides class (depositional vs. erosional, depositional vs. stable). When we estimated mean contaminant concentrations by reach, we observed higher contaminant concentrations in the furthest downstream reach with a decreasing trend in the two upstream reaches. Contaminant survey designs that account for sedimentation characteristics could increase the probability that sampling is allocated to areas likely to be contaminated.

#### TH068

##### **Assessment of organochlorine pesticides and PCBs in a multi matrix system from estuarine and its near-coastal areas of Argentina**

P.M. Oндarza, Universidad Nacional de Mar del Plata / Lab de Ecotoxicología y Contaminación Ambiental Depto Ciencias Marinas; L.B. Scenna, Instituto de Investigaciones Marinas y Costeras CONICET-Universidad Nacional de Mar del Plata / Lab Ecotoxicología y Contaminación Ambiental Depto Ciencias Marinas; V. Shimabukuro, Mar Del Plata National University; F.L. Lo Nostro, UBA & CONICET / PhD. Research assistant and teaching ass.; K.S. Miglioranza, University of Mar Del Plata / Lab of Ecotoxicology and Environmental Pollution

Estuaries are productive ecosystems exposed to an increasing pollution due to anthropogenic activities. The Bahía Blanca estuary (38°45' S-62°20' W) is one of the most economically important areas in Argentina, with an intensive agriculture production, commercial harbors and petro-chemicals industries. The environmental behavior of organochlorine pesticides (OCPs) and polychlorinated biphenyls (PCBs) in different biotic and abiotic matrixes was assessed in Rosales harbor (RH, inner site) and Pehuencó beach (PB, outside) of this estuary. OCPs and PCBs levels in water (N=12), suspended particulate matter (SPM, N=12), bottom sediments (BS, N=10), and the most abundant crab *Cyrtograpsus angulatus* (Varunidae) (N=18) were determined by GC-ECD. Concentrations are reported as ng/L in water, ng/g dry wt in SPM and BS, and ng/g wet wt in crab tissues. Water samples showed a predominance of OCPs in both sampling sites (3.7). SPM from PB presented a OCPs/PCBs ratio >1 (2.7) while those from RH was < 1 (0.4). BS from RH presented higher levels of OCPs and PCBs than PB. The pollutant levels in SPM were 200 and 80 times higher than BS in RH and PB, respectively. The highest OCPs concentrations were found in muscle samples (24.5-25.4) followed by gills (7.1-22.1) and hepatopancreas (4.3-8.1) of female crabs from PB, while

males showed the following distribution: gills (3.8) >hepatopancreas (4.3) >muscle (1.5). OCPs levels in males from RH decrease with the increment of the carapace width with the major difference in hepatopancreas of organisms with >30 mm (4.8) and < 25 mm (8.3), showing a dilution effect of pollutants. In all samples analyzed, endosulfans represented up to 70% of OCPs, with a a-/b-isomers ratio >1. This pattern indicates the technical mixture application for agricultural proposes, until their recently ban in Argentina. Enrichment in endosulfan sulfate was found in hepatopancreas of crabs in both sampling sites, suggesting the metabolism of the parent isomers in these organisms. The pollutants profile observed in crab tissues were similar to those found in water and BS, showing that *C. angulatus* is a suitable biomonitor for organic pollutants. This study revealed that land use in surrounding areas represents current sources of OCPs and PCBs to Bahía Blanca estuary. Consequently, future long-term monitoring programs in coastal areas are necessary in order to reduce the impact from agriculture and industrial activities on non-target communities.

#### TH069

##### **Formation and occurrence of the pyrethroid degradation product 3-PBA in urban environments**

J. Richards, University of California Riverside / Environmental Science; W. Jiang, California Environmental Protection Agency / Department of Pesticide Regulation; J. Gan, University of California, Riverside / Department of Environmental Science Pesticides are used in urban environments to control the populations of undesirable organisms such as ants and termites. The most intensive urban pesticide use occurs in areas like Southern California with a large human population density and a climate that allows pest species to be active almost year-round. For example, over 3.5 million pounds of pesticide active ingredients were applied to urban environments in California during 2012. In California, urban insecticide use is dominated by pyrethroids. While the occurrence of pyrethroid parent compounds has been widely documented in urban watersheds, the occurrence and formation of their degradation products has largely been ignored, even though their common metabolite 3-phenoxybenzoic acid (3-PBA) is a known endocrine disrupting compound. In this study, the formation of 3PBA was investigated by spiking concrete slabs with three different formulations containing permethrin and the concentration of 3-PBA in runoff was determined. The occurrence of 3PBA in urban waterways was also determined by collecting runoff samples from 6 locations in southern California, as well as in urban streams. Rapid transformation of concrete applied permethrin to 3-PBA was observed with 3-PBA levels in runoff exceeding  $100 \mu\text{g L}^{-1}$  even 3 months after the initial application. Similarly, the occurrence of 3-PBA in urbanized waterways was found to be widespread. These findings suggest that concrete surfaces may play an important role in the transformation of organic compounds, and that the inclusion of pesticide degradation products, such as 3-PBA, should be considered in monitoring and risk assessment in the future.

#### TH070

##### **Pyrethroid-Induced Oxidative Stress in a Model Social Insect**

L.J. Jenson, Entomology; D. Swale, Vanderbilt Medical Center / Anesthesiology; M.J. Lydy, Southern Illinois University-Carbondale / Center for Fisheries Aquaculture and Aquatic Sciences; T.D. Anderson, Virginia Tech / Entomology The honey bee (*Apis mellifera* L.) is the most widely managed crop pollinator in the United States providing the agricultural industry with the economic viability needed to satisfy the food and fiber needs of society. The annual losses of managed bee colonies are an enormous financial burden on the apiculture and agriculture industries. A perceived problem for the reduce number of bee colonies is the excessive use of agricultural and urban insecticides. Pyrethroid insecticides elicit oxidative stress via the unregulated accumulation of the reactive oxygen species in model insects. In turn, these reactive oxygen species can reduce immunocompetence, reproductive quality, and longevity in the insect. There are several gaps in our knowledge with respect to the effects of pyrethroid insecticide-mediated oxidative stress tolerance in bees. The ATP-sensitive potassium channels ( $K_{ATP}$ ) are a member of the inward-rectifying potassium channel ( $K_i$ ) family that provide cellular protection against oxidative stress. These  $K_{ATP}$  channels function as cellular osmoregulators to restore membrane potentials and to eliminate reactive oxygen species that accumulate during oxidative stress. Here, we will present the physiological mechanisms responsible for regulating oxidative-stress in bees following pyrethroid insecticide exposures. The  $K_{ATP}$ -mediated regulation of oxidative stress in pyrethroid-treated and -untreated bee genotypes will be reported using a classical pharmacological approach with  $K_i$  channel activating and deactivating compounds. We will discuss the use of these data to advance our understanding of the effects of insecticide exposures on bees, and the mechanisms that protect bees against these stressors in an effort to improve the health and productivity of bee colonies.

#### TH071

##### **Are neonicotinoids a threat for leaf litter breakdown? A laboratory approach with leaf shredding invertebrates**

D. Englert, Institute for Environmental Sciences / Institute for Environmental Sciences; M. Link, Universität Koblenz-Landau / Institute for Environmental Sciences; J.P. Zubrod, Institute for Environmental Sciences University of Koblenz-Landau / Institute for Environmental Sciences; R. Schulz, University of

Koblenz-Landau / Institute for Environmental Sciences; M. Bundschuh, Department of Aquatic Sciences and Assessment Swedish University of Agricultural Sciences / Department of Aquatic Sciences and Assessment Neonicotinoids are registered in over 120 countries for use against herbivorous insects in agriculture, horticulture, forestry, and tree nursery. Due to their extensive application and chemical properties, neonicotinoids are susceptible to be transported into surface waters via various pathways. There they might pose a threat to non-target species and associated ecosystem functions, such as the breakdown of leaf litter. This particular ecosystem function is critical in providing energy for local as well as downstream communities. To assess for potential risks of three frequently used neonicotinoid insecticides (imidacloprid, thiacloprid and acetamiprid) in this process, *Gammarus fossarum* (Amphipoda) and *Cheatopteryx villosa* (Trichoptera), two key leaf-shredding macroinvertebrates, were chosen as test species. These organisms were exposed to a range of neonicotinoid concentrations using their leaf consumption as endpoint. All experiments revealed a concentration-dependent decrease in the response variable, while the amphipod *G. fossarum* was 3 to 9 times more sensitive towards neonicotinoid exposure than the insect larvae *C. villosa*. Furthermore, when comparing the effective concentrations causing 20% reduction in feeding ( $EC_{20}$ ; expressed as  $\mu\text{mol/L}$ ), thiacloprid was – irrespective of the species investigated – the most toxic neonicotinoid. Moreover, for *Gammarus*, all three  $EC_{20}$  (1.7 to  $3.6 \mu\text{g/L}$ ) were in the range of field concentrations. Therefore, the present study indicates a risk for the leaf litter breakdown mediated by invertebrates, which might restrict the energy availability (in the form of feces) e.g. for collectors. Such implications may consequently reduce the prey availability for aquatic (e.g. fish) and – following the emergence of insects – terrestrial predators (e.g. spiders, birds, bats).

#### TH072

##### **Dietary exposure may increase the toxicity of roxithromycin in zebrafish (*Danio rerio*)**

J. Sohn, Seoul National University; S. Lee, Seoul National University / School of Public Health; H. Shin, Seoul Nation University; C. Kim, School of Public Health, Seoul National University; D. Jung, Seoul National School / Institute of Health and Environment; K. Choi, Seoul National University / School of Public Health Among various chemical exposure pathways, especially dietary exposure is one of the most important exposure pathways of bioaccumulative chemicals to aquatic organisms. However, studies involving dietary exposure have rarely been conducted for pharmaceuticals. Roxithromycin (RTM) is a widely detected antibiotic in aquatic environment, and is suspected for bioaccumulation. We conducted a food web exposure study on RTM in zebrafish (*Danio rerio*) employing *Artemia nauplii* as a feed. Zebrafish were exposed via water only (Group A) or via both water and food (Group B). Water concentrations were determined at 0.05, 0.5, or 5 mg/L following preliminary range finding tests. Dietary exposure was conducted using *Artemia* that were exposed to RTM at the same concentration for 24 hours after hatch. During exposure period, zebrafish were sampled on days 7 and 14, and were measured for molecular level markers of exposure to RTM. Transcription of *sod1* gene in liver tissue of zebrafish in Group B, showed positive trends both on day 7 and day 14. However, there were no significant differences in the transcription of *sod1* gene in Group A. Transcription of *cyp1a* gene was up-regulated in Group B on day 14, also the transcription of *cyp1a* in Group B was significantly increased at 5mg/L. However there were no significant change in Group A. The transcription of *cyp3a4* gene in liver tissue of zebrafish was up-regulated on day 7 in Group A. In brain, positive trends of *ache* gene transcription was found in Group B on day 7 but the difference disappeared on day 14. Overall, our results show that RTM can be transferred to fish through dietary exposure, and increase the adverse effects in fish. Food web exposure or secondary poisoning of pharmaceuticals should be considered in risk assessment of pharmaceuticals in aquatic environment.

## **Emerging Contaminants in the Marine Environment: Presence, Effects, Regulation (P)**

#### TH073

##### **Mapping of emerging and legacy polyfluorinated substances in sediment and investigation of their water-suspended sediment partitioning in a macro-tidal highly turbid estuary (Gironde, SW France)**

G. Munoz, LPTCEPOC 5805 CNRS / UMR EPOC LPTC; H. Budzinski, P. Labadie, University of Bordeaux / UMR EPOC Equipe LPTC Polyfluorinated substances (PFASs) are man-made chemicals that have been in use since the 1950s due to their excellent tensioactive properties. However, several PFASs have been reported to exhibit persistent, bioaccumulative and toxic properties; hence the interest in the analysis of these compounds in all environmental media. However, data for estuarine environments are scarce. Estuaries are complex systems, located at the land/sea interface, and are therefore of primary concern as regards the transfer of micropollutants to marine and coastal ecosystems. In this context, the 2014 HALOGIR campaign aimed at better understanding the ecodynamics of halogenated contaminants of emerging concern, including PFASs, in a macro-tidal highly turbid estuary. Located in the South West of France, the Gironde estuary was selected as our study site because of its ecological value, being home to a large number of diadromous and anadromous

fish, and the last known spawning site of the European sturgeon. The purpose of the present work was (i) to determine the PFAS contamination levels in the Gironde estuary, targeting both legacy and emerging compounds, (ii) to investigate the physico-chemical factors controlling PFAS levels in the water column (dissolved phase and suspended particulate matter (SPM)), and (iii) to extend and deepen knowledge of the physico-chemical factors controlling PFAS sedimentary accumulation. The sampling strategy consisted in a South-to-North transect, following a salinity gradient from the confluence of the Garonne and Dordogne rivers to the mouth of the estuary at Pointe-du-Verdon. A fine sediment deposition area, located approximately 25 to 50 km West to the mouth of the estuary, was also included in our survey to perform preliminary assessment of the PFAS transfer from the Gironde estuary to the Bay of Biscay continental shelf. The HALOIR campaign took place in early September 2014 and targeted 23 sampling locations. Subsurface and bottom water samples, as well as bottom sediment samples, were collected at each site. At the same time, 13 additional sediment samples were collected at low tide across tidal mudflats, on both banks of the estuary. Preliminary results indicate that PFASs were ubiquitous in the dissolved phase, 16/26 investigated PFASs being reported at sub ng.L<sup>-1</sup> levels. Following PFAS analysis of SPM and sediment samples, the influence of environmental variables on PFAS levels, patterns and partitioning will also be evaluated.

#### TH074

##### Occurrence and concentrations of benzotriazole UV stabilizers in sediments from industrialized coastal regions, South Korea

M. Rani, Korea Institute of Ocean Science and Technology; S. Hong, Korea Institute of Ocean Science and Technology / Oil and POPs research group; M. Jang, Korea Institute of Ocean Science and Technology / oil and POPs research group OPRG; G. Han, Korea Ocean Research and Development Institute / Oil and POPs research group; Y. Song, Korea Institute of Ocean Science and Technology; W. Shim, Korea Institute of Ocean Science and Technology / Oil and POPs research group

Benzotriazole UV stabilizers (BUVSs) are a class of plastic additives that are used in polypropylene and ABS (Acrylonitril, Butadiene and Styrene) copolymer products, which in turn are employed in building, automobile and consumer materials. Among several BUVSs, 2-(3-t-butyl-2-hydroxy-5-methylphenyl)-5-chlorobenzotriazole (UV-326), 2,4-di-t-butyl-6-(5-chloro-2Hbenzotriazole-2-yl) phenol (UV-327), 2-(2H-benzotriazole-2-yl)-4,6-di-t-pentylphenol (UV-328) are commonly used and toxic to animals (alterations in sex hormones, developmental effects etc.). The 2-(2H-benzotriazole-2-yl)-4,6-bis(1,1-dimethylethyl)-phenol (UV-320) is prohibited from production, usage and import, because of its potential for bioaccumulation and toxicities to liver and other tissues in laboratory mammals. However, environmental data on these compounds are still very limited. Therefore, level and distribution of these BUVs were investigated in sediments (n=84) from two highly industrialized coastal regions in South Korea i.e. Ulsan (n=47) and Busan (n=37) with different characteristics (i.e., population and potential source in the catchment). Their frequent detection ranged from n.d.-174 (UV-320), n.d.-168 (UV-326), n.d.-139 (UV-327) and 0.1-168 ng/g dw (UV-328) indicated widespread use. The overall average concentration was highest for UV-320 (19.2±34 ng/g dw) followed by UV-328 (14.6±26 ng/g dw), UV-327 (8.9±19 ng/g dw) and UV-326 (6.9±22 ng/g dw) pointed out concern for possibly affecting the vital activities of the marine animals via BUVs. The concentration of BUVSs was higher in Ulsan than that of Busan. Industries followed by harbor and river discharge can be recognized as BUVs input sources to marine environment. At both regions, the BUVSs concentrations showed a negative gradient from land (source) toward offshore region, indicating land based activities are the main source of BUVSs to the marine environment. Widespread detection of these contaminants of emerging concern in marine sediments suggests that these chemicals have the potential to migrate out of consumer products and enter the outdoor environment.

#### TH075

##### FABRIC PHASE SORPTIVE EXTRACTION (FPSE) FOLLOWED BY UHPLC FOR THE ANALYSIS OF UV STABILIZERS IN AQUEOUS SAMPLES FROM GRAN CANARIA ISLAND (SPAIN)

S. Montesdeoca-Esponda, Departamento de Química; R. Guedes-Alonso, Universidad de Las Palmas de Gran Canaria / Chemistry; Z. Sosa-Ferrera, Universidad de Las Palmas de Gran Canaria / Departamento de Química; A. Kabir, Universidad de Las Palmas de Gran Canaria; K.G. Furton, Florida International University; J. Santana-Rodríguez, Universidad de Las Palmas de Gran Canaria / Departamento de Química

Fabric phase sorptive extraction (FPSE) is a novel sample preparation technique developed by Kabir and Furton [1]. FPSE is a highly sensitive, fast, efficient and solvent minimized sample preparation approach [2] that integrates the advantages of sol-gel derived hybrid inorganic-organic sorbents and the flexible, permeable and rich surface chemistry of cellulose fabric. FPSE media contains approximately 400 times higher sorbent loading than SPME fibers, providing better extraction efficiencies. Moreover it is a cheap device that can be reused and do not suffer from coating damage, often encountered in SPME fibers or stir bars. Unlike SPME or other microextraction techniques, FPSE mimics solid phase extraction (SPE) by allowing permeation of aqueous sample matrix through its extraction media, resulting in a near-exhaustive extraction (with very high absolute recovery of

analytes) in a short period of time. Benzotriazole UV filters are a group of compounds added not only in sunscreen but also in variety of personal care products, which present negative effects over aquatic systems. They are mutagenic in bacterial systems and toxic in plants and can exert adverse effects on the fecundity and reproduction of fish [3]. We optimized the extraction of seven benzotriazole UV filters evaluating three different FPSE sorbent chemistries (polyethyleneglycol, polytetrahydrofuran and polydimethyldiphenylsiloxane). All the parameters involved in the extraction were tested, such as extraction time, desorption time, desorption solvent and ionic strength. The extraction procedure was followed by ultra-high pressure liquid chromatography with mass spectrometry detection. Once optimized the sample preparation and analysis procedure, the analytical parameters were evaluated and it was applied to determine the presence of seven benzotriazole based UV filters in aqueous samples from Gran Canaria Island (Spain). #### TH076

##### Occurrence of PFAS in the European eel (*Anguilla anguilla*) from the Loire estuary (France)

M. Couderc, Université de Nantes; I. Poirier, MMS EA; A. ZALOUK-VERGNOUX, Université de Nantes; A. Kamari, Université de Nantes; I. Blanchet-Letrouve, MMS EA; P. Marchand, A. Venisseau, ONIRIS / LABERCA; B. Veyrand, ONIRIS; C. Mouneyrac, Université Catholique de l'Ouest / MMS EA; B. Le Bizec, ONIRIS / LABERCA

The perfluorinated and polyfluorinated alkyl substances (PFAS) are largely used as additives for the production of fluoropolymers and as surfactants in industrial and consumer products. The PFAS were basic components in the production of carpets, textiles, paper and packaging products. For these emerging contaminants, the Water Framework Directive of the European Commission has set environmental quality standards (EQS) in surface waters (river, lake, transitional and coastal) in 2013. The EQS are the concentrations of pollutant(s) in water, sediment or biota which should not be exceeded in order to protect human health and environment. Among the potential indicator species, the eel may be used. The European eel has specific physiological and behavioral characteristics favorable for the use as chemical sentinel species. As eel pollution profiles were shown to be significantly different along a river at small and large-scale, it would be a valuable fingerprint of the chemical pressure of a specific site, particularly for the lipophilic chemicals. Furthermore since 1950, the eel population has continued to decline. In this context, the PFAS contamination of the Loire estuary was investigated in muscles of European eel (*Anguilla anguilla*). Yellow eels (n=30) were caught in three different locations along the estuary to highlight variations between sites and sources of contaminations. Silver eels (n=15) were also studied to compare contaminant impregnation between different life stages of the species. Average concentrations in muscles of the eel ranged between: 130-1293 ng/g LW for the PFAS. Perfluorooctanesulfonic acid (PFOS) was the most widely detected PFAS (85%). About 75% of the eels exceeded the EQS for biota specific to PFOS. The presence of PFAS and particularly of PFOS in eels from the Loire could be explained by the industrial activities around the estuary (wood transformation, especially paper industry and for metal surface treatment industry). Regarding the spatial and the life stage differences, no significant differences between the PFAS were observed due to the very high variability of the concentrations of these groups. These results supplied new data on the occurrence, levels, and patterns of PFAS in the eels from the Loire estuary and they highlighted the need to further investigations focused notably on the potential effects of these chemicals on this species and their analysis in the water and sediments of the estuary.

#### TH077

##### Selected PPCPs determination in Chilean marine species

A. Giordano, Pontificia Universidad Católica de Chile; M. Retamal, Universidad de Chile; D. Peñalzo, SP Technical Research Institute of Sweden / Wood Technology; L. Urzua, Universidad Tecnológica Metropolitana

Pharmaceutical and personal care products (PPCPs) have been detected in diverse environmental matrices and a better knowledge of their occurrence became necessary. This concern has led to the determination of PPCPs in marine species. Concentration of  $\beta$ -estradiol, ibuprofen, carbamazepine along with some sunscreen have been recently measured in Chilean marine products. In particular we analyzed tissues of austral hake (*Merluccius australis*), atlantic salmon (*Salmo salar*), Chilean abalone (*Concholepas concholepas*), and piure (*Pyura chilensis*), particularly fillet and liver from the fish. Samples were collected in Southern Fall 2014 from several fisheries in the IV Region of Chile, extracted by QUECHERS methodology and determined by GC-MS with a previous derivatization step. Analytical issues of the extraction methods and its limitations were examined in order to obtain high recoveries. Preliminary results indicate that levels of PPCPs were very low or not detected for most of the compounds. Final results will be discussed and related with lipid and protein content in the different tissue samples.

#### TH078

##### Australian humpbacked dolphins (*Sousa spp*) - Using stranded animals to

#### **prioritise PBT analytes in biopsies for critically threatened species**

F. Neugebauer, Eurofins GfA Lab Service GmbH / RD; C. Gaus, National Res. Centre for Environmental Toxicology / Public Health Department; N. Lohmann, Eurofins GfA Lab Service GmbH; J.J. Meagre, Queensland Government / Department of Environment and Heritage Protection; O. Paepke, Eurofins GfA Lab Service GmbH

Apart from concern for human health, the general ecological state of an ecosystem is strongly reflected by animal health, especially for animals at higher trophic levels. The burden of persistent organic pollutants (POPs) and similar compounds in marine animals living in proximity to industrialised coasts is a commonly used indicator of the contamination status of such environments. Especially interesting POPs are the polychlorinated dibenzo-*p*-dioxins and -furans (PCDD/Fs) and polychlorinated biphenyls (PCBs) which show a high toxicological potency in animals and humans. 2,3,7,8-TetraCDD and PCBs in general have meanwhile been classified as carcinogenic to humans (IARC 2007; 2013). Furthermore important, since they may be released from ships coatings, is the analysis of organotin compounds (OTC), as well as typical agricultural chemicals such as persistent organochlorine pesticides, and combustion by-products such as PAHs. In the last couple of years there have been increased stranding incidents of various threatened marine wildlife species along the Australian east coast. Elevated mortality rates of the rare Australian Indo-Pacific humpbacked dolphin (*Sousa spp*) were observed around Moreton Bay, where 12 stranded individuals (out of an population of estimated ~120 individuals) have been found in 2011-2013. Concern has been raised about their exposure to persistent and toxicologically relevant substances since *Sousa spp* feeds in shallow habitats, e.g. estuaries. In order to determine whether contaminant exposure is of concern, and to prioritise which compounds should be monitored in future biopsy sampling, fat and other tissue samples from some of the stranded individuals have been analysed for PCDD/Fs, dl-PCBs, ndl-PCBs, OTC, PAHs and certain organochlorine pesticides. The results indicate high levels of some of these analytes, especially PCBs. Key words: Dioxins, humpback dolphins, PCBs, organotin compounds, PAHs, organochlorine pesticides

#### **TH079**

##### **A multibiomarker approach to evaluate caffeine effects on *Mytilus galloprovincialis***

M. Capolupo, A. Kiwan, University of Bologna / CIRSA via S Alberto Ravenna; P. Valbonesi, University of Bologna; E. Fabbri, University of Bologna / Bigea Department via Selmi Bologna

The greatest part of the total amount of marketed caffeine (CF) is orally consumed through coffee, tea infusions and other beverages, whereas to a lesser extent is employed therapeutically as active ingredient of a variety of pharmaceuticals against cerebral, cardiovascular and urinary disease. Being released through anthropogenic sources as rapidly as it is dissipated, CF has been found to be one of the most ubiquitous and “pseudo-persistent” compounds within surface waters. It is found in waters worldwide at environmental concentrations comprised in the range of 2-1600 ng/L, with higher values measured in estuarine and coastal waters. Increasing questions have recently been raised as to whether standard ecotoxicological test are able to provide a realistic insight of the adverse outcomes potentially triggered by pharmaceuticals on aquatic ecosystems. To approach a more sensitive and predictive assessment of ecologically relevant effects triggered by pharmaceuticals on aquatic environment, the use of biomarkers of environmental stress was suggested. The present study aimed at investigating sub-lethal effects induced by exposure to environmentally relevant concentrations of CF on the Mediterranean mussel *Mytilus galloprovincialis*, treated with 5, 50 and 500 ng/L CF (nominal concentrations) for 7 days. CF final concentrations were measured in aquaria, and CF accumulation were evaluated in tissues. Through a multi-biomarker approach, lysosomal membrane stability (LMS), along with lipofuscin and neutral lipids content, were measured to assess potential alterations on the general health status of mussels. Pro-oxidative effects and detoxification response were screened by the analysis of catalase and glutathione S-transferase (GST) activities and malondialdehyde tissue accumulation, whereas acetylcholinesterase activity, and heat shock protein expression (HSP70) were analyzed to assess the onset of neuro- and cyto- toxic injuries, respectively. No changes were observed in any of the above parameters, except for LMS which was significantly reduced, and GST activity which was significantly increased at the highest tested concentrations. Overall, present data suggest that CF at environmental concentrations is a substance of lower concern with respect of other pharmaceuticals (i.e fluoxetine and carbamazepine), that we previously studied.

#### **TH080**

##### **Effect of pyrethroid treatment against sea lice in farmed salmon**

. Aznar-Alemany; E. Eljarrat, IDAEA-CSIC / Department of Environmental Chemistry; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research

Pyrethroids are organic pollutants with high hydrophobicity used as insecticides. Concern exists about aquatic organisms exposure to their toxicity. They were believed to be converted to non-toxic metabolites in mammals, but our group has detected them in human breast milk and has proved their bioaccumulation in marine mammals and river fish. Chemical inputs from aquaculture activities may include prescribed pesticides and drugs, antifoulants, anaesthetics and disinfectants. The recommended treatment of salmon against sea lice is with pyrethroids, specifically

cypermethrin and deltamethrin baths. The objective of this work was to study the impact of pyrethroid treatments in farmed salmon by comparing their pyrethroid levels and profiles with those of wild salmon. Differences between the possible presentations of the salmon—smoked, marinated, fresh, packed and frozen—were assessed as well. An average daily intake was also estimated and compared to the acceptable daily intake (ADI) of pyrethroids. Over 40 samples of salmon from Norway, Scotland, Spain, France, Denmark and Chile were purchased at retail stores and fishmonger's, including four species. The analytical method monitored 10 pyrethroids, including cypermethrin and deltamethrin. For the sample preparation lyophilized salmon was spiked with internal standards, extracted by sonication and underwent a clean-up with alumina and C18 SPE cartridges. Extracts were analysed by GC-NCI-MS/MS. Method recoveries for the pyrethroids ranged 53-116 % and method LODs and LOQs were 0.02-0.46 ng/g and 0.08-1.54 ng/g, respectively. Up to 8 pyrethroids were found in 100 % of the farmed samples and 66.7 % of the wild salmon with total pyrethroid concentrations ranging 5-45 ng/g in lipid weight (lw) and 0.5-6 ng/g in wet weight (ww). Levels in farmed salmon—with outstanding amounts of permethrin and deltamethrin—were significantly higher than in wild salmon. Having evaluated accumulation of insecticide pyrethroids in salmon for the first time, data suggest that there is no significant difference between the pyrethroid profiles of farmed salmon according to origin, species or presentation. Average daily intake was estimated for individual pyrethroids considering 94.9 g/day fish consumption for a 67.5 kg person. The estimated values were 4-5 orders of magnitude safely below the ADIs.

#### **TH081**

##### **Solid bulk cargo shipping - an overlooked threat to the marine environment?**

M. Grote, BfR / Transport of Dangerous Goods; N. Mazurek, Bundesinstitut für Risikobewertung BfR / Transport of Dangerous Goods; J. Zeilinger, Institute of Ecopreneurship, University of North-West Switzerland; T. Höfer, Bundesinstitut für Risikobewertung BfR / Transport of Dangerous Goods

Maritime transport is the backbone of the World Economy. In 2013, approximately 9.5 billion tons of goods (more than 90% of world trade) were loaded for seaborne transport in ports worldwide. Solid bulk represents the largest group accounting for more than 50% of all loaded goods. The International Convention for the Prevention of Pollution from Ships, (“MARPOL”) aims to minimize pollution of the seas, including dumping, oil and exhaust pollution. Unlike for liquid bulks (such as oils) or packaged goods, there has not been any specific anti-pollution regulation concerning dry bulks. The recently amended MARPOL Annex V now prohibits disposal of cargo residues classified as Harmful to the Marine Environment (HME). However, a comprehensive hazard and risk assessment of goods transported in bulk is lacking. The aim of the present study is to analyse whether the transport and the associated inputs of solid bulk into the marine environment represent a potential threat for the marine ecosystem and/or human health. For this purpose, we analysed publicly available information on discharge quantities, identities and composition of schedules shipped as solid bulk and derive a marine hazard and risk assessment. Currently, it is a routine practice to discharge cargo residues of 60 tonnes and more on board a single solid bulk carrier after unloading. Total inputs of solid bulk into the marine environment were estimated to exceed 5 million tons per year.

According to the HME criteria in the MARPOL Annex, the majority of schedules listed in the guidance document for shippers (the IMSBC Code) are classified as non-HME (agricultural and forestry goods, many salts, mineral ores and refined metals). Others potentially meet the HME criteria (chopped or ground plastics or rubber, several ores or alloys containing heavy metals) or have an ambiguous composition, (mineral concentrates, pitch prill, etc.), which hamper identification of its (eco-)toxicological characteristics. Overall, the availability of information necessary for marine risk assessment is limited. Comparatively little attention has been devoted to solid bulk risk assessment by the scientific community. However, we believe the massive inputs in combination with their ambiguous composition and the unclear bioavailability should be seen as an obligation for a better quantification of inputs, exposure and hazard of respective material in order to perform a more conclusive risk assessment.

#### **TH082**

##### **Spatial distribution of hydrophobic organic contaminants in bulk marine sediment-porewater systems and the effect of grain size in the North Sea**

B. Brockmeyer, German Federal Maritime and Hydrographic Agency (BSH); N.C. Niehus, Hamburg University of Applied Sciences (HAW) / Department of Environmental Engineering; N. Theobald, BSH / Marine Chemistry; G. Witt, HAW Hamburg / Department of Environmental Engineering

The ability of sediments to adsorb organic contaminants makes sediment analysis a valuable tool to track contaminant migration in marine environments. This ability largely depends on the grain-size distribution of sediments, whereby fine-grained sediment absorbs contaminants more readily than coarse-grained sediment. Additionally, organic contaminants equilibrate between sediment and sediment porewater. This inside partitioning of hydrophobic organic contaminants in marine sediments-porewater systems is of special interest in terms of pollutants bioavailability. The fraction sorbed to sediment is less biologically available for organisms than freely dissolved concentrations in porewater ( $C_{free}$ ). Therefore, we examined the spatial distribution as well as the inside sediment and sediment-porewater partitioning of 5 polychlorinated biphenyls (PCBs) and 11 polycyclic aromatic hydrocarbons (PAHs) in representative sediments from

gravely sand to sandy mud of the North Sea (German EEZ). Concentrations of PCBs are closely related to the distribution of TOC ( $R=0.91$ ) and fine grained material ( $R=0.75$ ). PAH distribution is also affected by grain size ( $R=0.84$ ) and TOC ( $R=0.69$ ). Furthermore, the partitioning of PCBs and PAHs between sediment and  $C_{free}$  reveals that lower molecular weight PCBs and PAHs predominate  $C_{free}$ , while higher molecular weight PCBs and PAHs predominate sediment. On a logarithmic scale the sediment-porewater partition coefficient correlates significantly (PAH:  $R>0.92$ , PCB:  $R>0.89$ ) with the octanol-water partition coefficient, indicating that the pollutants bioavailability depends on its physicochemical properties, e.g. water solubility.

## Challenges for environmental risk assessment of nanomaterials: addressing knowledge gaps, protection goals and regulatory perspectives (P)

### TH084

#### Regulation of Nanomaterials under REACH

C. Constantin, ECHA-European Chemicals Agency / Evaluation Directorate; Z. Kloslova, L. Deydier, European Chemicals Agency ECHA / Evaluation Directorate; A. Kapanen, European Chemicals Agency - ECHA

Nanotechnology is a rapidly emerging field that involves the manufacture and use of materials at the nanoscale, typically between 1 and 100 nanometres, to create materials, devices, and systems which may have fundamentally new properties and functions. In the EU, NMs are implicitly covered by the substance definition of REACH Regulation 1907/2006 although currently REACH doesn't explicitly lay down specific rules for NMs. Until now there is still remaining issues to be resolved of how the specific challenges and unique features existing at the nanoscale have to be tackled and distinctively addressed, given that they may substantially differ from those encountered with bulk materials. As a regulatory agency the European Chemicals Agency (ECHA) plays a proactive role in the international regulatory debate on NMs by providing scientific input and support. To implement REACH, CLP and BPR in the EU, ECHA currently uses two approaches; first being supportive, providing help and advice through webinars, workshops and bilateral discussions with the Registrants of NMs and the second a formal approach where by using the legal instruments already available under REACH (substance/dossier evaluation, authorisation and restriction). Under REACH a registration dossier has to be submitted if a substance is produced/imported in volume higher than 1 ton/year and a Chemical Safety Report has to be prepared if the volume is higher than 10 ton/year. The registrant may either chose to register the nanoform in the dossier of the bulkform or submit a specific a separate dossier for the nanoform. Through a compliance check process potential data gaps can be addressed and the necessary information requested to bring the dossier into compliance with REACH obligation. Thus, through registrant fulfilling the legal obligations in REACH, data and information on the safe use and potential hazards should be generated. Moreover, under REACH, a substance for which concerns have been identified at community level, such substance may be subjected to substance evaluation process. The same reasoning and process may also apply to a nanomaterial or a substance containing nanoforms in the scope of the registration. Under Substance evaluation process, Member States evaluate certain substances to clarify whether their use poses a risk to human health or the environment. The objective is to request further information from the registrants of the substance to verify the suspected concern, if necessary.

### TH085

#### Regulatory Challenges in Risk Assessment of Nanomaterials

K. Halling; A. Kapanen, European Chemicals Agency - ECHA; C. Constantin, ECHA-European Chemicals Agency / Evaluation Directorate; G. Falck, B. Quinn, O. Rahkonen, A. Sumrein, F. Le Curieux, J. Holmqvist, ECHA European Chemicals Agency

In October 2014 ECHA organised a Topical Scientific Workshop on Regulatory Challenges in Risk Assessment of Nanomaterials in Helsinki. During this 2-day workshop, ECHA fostered discussions on the possible regulatory impacts of the latest scientific developments in risk assessment of nanomaterials. One of the objectives of the workshop was to identify new or improved approaches in the context of risk assessment of nanomaterials that can be utilised in a regulatory context. Discussions on regulatory challenges were built around five topics addressing current challenges of risk assessment within different regulatory regimes, measurement and characterisation on nanomaterials, metrology and use of different dose metrics in hazard and exposure assessment, environmental hazard and fate assessment, and read-across and categorisation. This presentation will cover the outcome of the discussions of the workshop highlighting issues such as the applicability of specific dose metrics, environmental fate descriptors and challenges with applied test methods in hazard and fate assessment, and related research needs from a regulatory perspective. In addition, challenges related to read across and categorisation of nanomaterials will be addressed. ECHA will take on-board the conclusions from the workshop in future work and continue exchanging experiences with EU member states, the scientific community, industry and other stakeholders both in the EU as well as on an international level. It is foreseen that the discussions taken place at the workshop will be considered in the

drafting of ECHA guidance for registrants and lead to further actions related to approaches taken in the risk assessment of nanomaterials.

### TH086

#### Dynamic simulation of engineered nanoparticles in the river Rhine.

A. Markus, University of Amsterdam / IBEDESS; J. Parsons, P. de Voogt, University of Amsterdam / IBED; E. Roex; R. Laane, DELTARES

Nanoparticles can enter the aquatic environment by several pathways, for instance via the effluent of wastewater treatment plants or via indirect discharge of wastewater. While these are not the only routes, they are probably the most important ones for several common types of nanoparticles. Of the many different types of nanoparticles that are being examined for incorporation into consumer and industrial products and that are actually being used, titanium dioxide, zinc oxide and silver nanoparticles are among the most common. Both titanium and zinc are found in abundance in the environment, either from natural causes or because of use in traditional products. Silver is somewhat rarer than the other two, but even that can be found in a typical European river. The question that is investigated here is: can we predict the actual concentrations of these types of nanoparticles in a river like the Rhine and what is the relative contribution of nanoparticles to the water quality of such a river? The information on which such a prediction is to be based includes: data on the total loads of these three metals, derived from measurements, estimates of the loads of nanoparticles from consumer products and an understanding of the processes that nanoparticles are subject to. Using this information and a numerical model for the river Rhine we were able to simulate the concentration of several substances, including the three types of nanoparticles. A comparison of the model results for suspended matter, zinc and PCB-153 with available measurements shows that the model is quite capable of simulating the transport of these substances. This gives confidence in its ability to simulate the transport of nanoparticles, for which no measurements are available. The results indicate that nanoparticles can be transported over long distances, eventually reaching the sea.

### TH087

#### Temporal and spatial trends in engineered nanoparticle mobility and transformations in a watershed model

A.L. Dale, Engineering and Public Policy; G. Lowry, Carnegie Mellon University; E. Casman, Carnegie Mellon University / Engineering Public Policy

An adaptation of the USEPA-supported Chesapeake Bay Watershed Model is linked to the WASP7 water quality modeling suite in order to explore the impact of spatial and temporal trends in land use, precipitation, stream flow, sediment transport dynamics, and water quality on the reactivity and mobility of silver (Ag) and zinc oxide (ZnO) engineered nanoparticles (ENPs) released to the James River Basin in Virginia, U.S.A. following sewage treatment. The model compares direct effluent discharges to surface runoff of land-applied biosolids containing realistically transformed ENPs and predicts ENP transport and speciation in river reaches and sediment bed layers over two decades. Fertilizer runoff is shown to account for a significant fraction of total metal stream loads from ENP sources. Due to high flow-through and bed resuspension in much of the basin, only a small fraction of the total metal mass input to the basin remains at the end of the simulation. However, significant accumulation occurs locally where loads are high and stream velocities are low. Silver from ENPs persists as  $Ag_2S$ , whereas zinc exhibits complex speciation. Total metal concentrations from ENP sources fall below USEPA water and sediment quality guidelines in all cases, suggesting that current ENP releases do not pose a significant environmental risk in temperate freshwater systems such as the one considered here.

### TH088

#### Targeting research based on ecological risk assessment needs for nanomaterials

Y. Sultan; N. Khera, N. Davidson, Environment Canada

Environment Canada has been regulating nanomaterials under the New Substances Notifications Regulations (Chemicals and Polymers) since 2007. Over these past 8 years, research in support of ecological risk assessment has been adapted to reflect domestic and international needs. From 2007-2012, Environment Canada focused on supporting research to feed not only into our domestic programs but also directly into the Organization for Economic Cooperation and Development (OECD) Working Party on Manufactured Nanomaterials (WPMN) Sponsorship Program. Since 2012, Environment Canada's nanoscience program has been focused on identifying key parameters to predict environmental fate and toxicology. This poster will present the evolution of nano research (i.e., moving beyond method development and focusing on key determinants and categorization frameworks to inform safety) supported by Environment Canada and how it continues to directly impact Environment Canada's regulatory program.

### TH089

#### Test strategy with regard to the environmental risk assessment of nanomaterials considering regulatory approaches

K. Hund-Rinke, M. Herrchen, Fraunhofer IME; K. Schlich, Fraunhofer IME - Institute for Molecular Biology and Applied Ecology

Aim is the proposal of a test and environmental risk assessment strategy for

engineered nanomaterials (ENM) addressing the aspects fate and effect. The proposed IME-test strategy and risk assessment approach is a life-cycle oriented one, and thus considers all stages along the life of the ENM. For each single stage it has to be considered whether there is a potential for the ENM to be released into the environment. Furthermore, the initial environmental compartment the ENM is released into has to be identified. If the release potential is negligible, this particular life-cycle stage needs no further consideration. In case the ENM is released into the environment its durability in the initial compartment should be screened (tier 0). For that screening any information on the changes or loss of ENM properties is indispensable. In case low durability is ascertained, i.e. the ENM rapidly loses its nano-material properties, the formed chemicals can be handled as conventional chemicals. In case medium to high durability is stated, the first tier of the assessment scheme is entered. On tier 1, both a fate and effect assessment is performed. The assessment results in a predicted environmental concentration in the initial compartment ( $n\text{-PEC}_{\text{ini}}$ ) and a predicted no effect concentration ( $n\text{-PNEC}$ ). The deduction of  $n\text{-PEC}_{\text{ini}}$  needs the information on parameters which determine medium to high durability, and also on the amount of the ENM released as well as on the production volume. It furthermore needs a setting of the size of the initial compartment, e.g., the definition of a local or regional scenario as well as other information such as dispersion stability and PC-properties of the pristine ENM. The effect assessment is based either on screening tests (in case of low production volume) or on tests using OECD test-guidelines (in case of high production volume). Thus, the effect testing on tier 1 comprises two different levels of complexity. Besides  $n\text{-PNEC}$ -values a classification and product labelling (CPL) can be suggested on the basis of the effect concentrations and comparably to conventional chemicals, a risk quotient ( $n\text{-PEC}_{\text{ini}} / n\text{-PNEC}$ ) can be formed. The refined  $n\text{-PNEC}$ -assessment on tier 2 comprises a higher tier testing. The suggested test strategy has been developed based on the knowledge of (inter)national publications and discussions. It also takes into account the conclusions made by the OECD WPMN on ecotoxicity and environmental fate (Berlin, January 2013).

## TH090

### Toward relevant risk assessments for nanotechnologies: Screening tools and tiered-based testing frameworks

A.J. Kennedy, CEERD-EPR; S.A. Diamond, NanoSafe Inc. / Midwest Division; Z. Collier, US Army Corps of Engineers / Engineer Research & Development Center; J.G. Coleman, US Research and Development Center / Environmental Laboratory; R. Moser, Georgia Institute of Technology; A.R. Poda, US Army Engineer Research and Development Center; M.A. Chappell, U.S. Army Corps of Engineers / Environmental Laboratory; A. Bednar, US Army ERDC; J.K. Stanley, U.S. Army Engineer Research and Development Center / Environmental Laboratory; J.A. Steevens, U.S. Army Engineer Research & Development Center / Environmental Laboratory

The emergence of engineered nanotechnologies necessitates a better understanding of their potential environmental, health, and safety effects before wide-scale technology deployment. However, the properties of nanomaterials and uncertainty regarding applicable test methods has led to lack of consensus regarding the collection and evaluation of data related to hazard and exposure potentials. While efforts are underway to categorize nanoparticles by their unique properties to form logical management units, procedures for screening technologies and consistent, yet adaptive testing procedures are needed in the interim. ERDC is developing a logical, tiered approach (NanoGRID) for generating the most relevant data to feed risk assessment of nanotechnologies that is inspired by current dredged sediment testing strategies. Briefly, tier 1 consists of categorization of technologies, tier 2 consists of relevant use and release population, tier 3 involves determination of environmental persistence, tier IV consists of hazard assessment and tier 5 applies case specific investigations. The tiered testing process can terminate once sufficient risk-related information has been collected, or the process provides lines of evidence that the technology in question does not require nano-specific scrutiny. The tiered, adaptive guidance approach allows users to concentrate on collecting the most relevant data, thus accelerating technology deployment while minimizing risk. In addition, we are developing a web-based tool suite (NanoExPERT) that provides fundamental particle fate and toxicology estimation; these screening tools allow visualization of available data to determine relevant toxicity thresholds and assist in determining when additional data generation is needed. Tools in the suite allow estimation of particle dissolution, DLVO behavior, particle number-density, crystalline face surface area, bioaccumulation factors, and toxicity visualization and screening, a modifying environmental factor function, and a dose metric converter. Each tool is limited only by a database containing bench top or literature data and output is user selectable. These tools are used a component of the tiered, adaptive guidance framework.

## TH091

### Providing comprehensive information on environmental impacts of nanomaterials - The DaNa2.0 Knowledge Base Nanomaterials

D. Kühnel, Helmholtz-Centre for Environmental Research / Bioanalytical Ecotoxicology; K. Nau, C. Marquardt, Karlsruhe Institute of Technology KIT / Inst Applied Computer Science; H.F. Krug, EMPA; F. Paul, DECHEMA; C. Steinbach, University of South Bohemia in Ceske Budejovice

Assessing the impact of new technologies or newly developed substances on our environment is a challenge, even more so if the applied test methods - both

toxicological and analytical - are often found to be inadequate and need amendments as it is in the case of nanotechnology. This is illustrated by numerous publications in the field of nano-ecotoxicology which although they have been investigating the impact of a number of nanomaterials on several organisms almost never allow for explicit statements on potential hazards. This fact not only hampers the knowledge communication to all non-scientists (e.g. consumers) but it also complicates the transfer of the obtained results for other scientists. Hence, reliable and understandable information on nanomaterials and nanotechnology is often missed, e.g. on the basic questions: *What exactly are nanoparticles? What is meant by "exposure"? When do toxicologists speak of a risk?* These and many more questions are answered by our web-based knowledge base: [www.nanoobjects.info](http://www.nanoobjects.info). In an interdisciplinary approach scientists of the DaNa expert team provide a knowledge base for more transparency wrapping up the results of current research on nanomaterials regarding their influence on humans and the environment in an understandable way. Our presentation of complex scientific data addresses not only the scientific community but is also intended for the broader public, e.g. consumers, journalists, students or scientists from other research areas. In order to facilitate the evaluation process of scientific publications a methodology based on quality criteria was developed. Furthermore, the DaNa-project acts as an umbrella project for current projects funded by the BMBF (German Federal Ministry of Education and Research) with regards to nanotechnology and their ecological benefits. The collected knowledge integrated into the DaNa database could also contribute to the prioritisation of further research needs. DaNa on Twitter: @nano\_info. Kühnel, D. et al. ## TH092

### Closing the gap between exposure and effect assessment of engineered nanomaterials

J.T. Quik, RIVM / DMG; I. Velzeboer, Wageningen University; E. Tsitsiou, Faculty of Earth and Life Sciences VU University / Dept of Ecological Sciences; D. De Zwart, RIVM / Centre for Sustainability Environment and Health; D. van de Meent, RIVM / DMG

For environmental risk assessment a relevant expected exposure concentration is compared with an estimate of the safe concentration of a chemical. For engineered nanomaterials (ENMs) this is usually done with a total concentration of ENMs, e.g. not distinguishing between primary ENMs, aggregates and heteroaggregates. However, it is thought that under environmental conditions ENMs will primarily be present as either aggregates or heteroaggregates attached to natural particulate matter. This is already incorporated in several models that predict exposure concentrations (PECs) in the environment for each of these ENM forms: primary ENMs, ENM aggregates and ENM heteroaggregates. In the effect assessments it is usually unclear whether the resulting no effect concentration or other endpoint is related to a specific form of ENMs. Most of the currently available effect endpoints are related to aggregates of ENMs based on the reported ENM hydrodynamic radius in the exposure media. However, no effect endpoints where related to ENM heteroaggregates which are thought to be the prevailing form of ENMs under most environmental conditions. We show the difference between PEC/PNEC ratios of total ENM concentration and taking the different forms into account. Data is needed on PNEC's derived for ENM heteroaggregates.

## TH093

### A Nanomaterial by Definition: Ecotoxicology Hazard Characterization and Environmental Risk Assessment of an Organic Pigment

E. Lammer; E. Salinas, BASF SE; U. Veith, BASF Schweiz AG; K. Wiench, BASF SE

Nanotechnology is regarded as one of the key enabling technologies of the 21st century. To fully realize the benefits of any "new" technology the associated risks to humans and the environment must be addressed. The unique physical properties of some nanomaterials raised concerns that "nano-specific" toxic effects may result from exposure to such materials. Despite an abundance of research over the last decade focused on nanomaterial safety, specific nano toxic effects have not been identified in animal model systems; the difference is only of quantitative nature. Nanomaterials are chemicals and as with all chemicals some will be toxic at regulatory relevant concentrations and others not. Compared to human health aspects there are very few publications which specifically address the environmental risk assessment of nanomaterials. However, diketopyrrolopyrrole (DPP) pigments are a well evaluated group of chemicals, many of which fall within the boundaries of the ISO definition and EU Recommendation for nanomaterials. Various DPP pigments were tested in short-term and chronic aquatic tests and terrestrial systems showing only a low toxicity. In addition, no bioaccumulation potential of these pigments could be demonstrated. Here we present as a case study an environmental risk assessment with a DPP pigment showing no risk for the environment in various uses. We discuss the challenges facing industry and regulators in assuring the accurate characterization of ecotoxicological hazard and the use of those data in meaningful environmental risk assessments in relation to nanomaterials.

#### TH094

##### **Long-term effects of uncoated silver nanoparticles on the sediment-dwelling polychaete *Capitella teleta***

M.B. Nielsen; A. Palmqvist, Roskilde University / Department of Environmental Social and Spatial Change; V.E. Forbes, University of Nebraska Lincoln / School of Biological Sciences; A. Gergs, RWTH Aachen University / Department of Environmental Social and Spatial Change

The increasing application of nanoparticles in consumer products has led to increasing concerns about their potential environmental risks. When released to the environment a great proportion of nanoparticles are predicted to end up in the aquatic environment and deposit in the sediment. Knowing the effects of nanoparticles on sediment-dwelling organisms is therefore an important step towards assessing the risks of nanoparticles. Information about the toxic effects of nanoparticles is in many cases still insufficient to carry out proper risk assessments and an example is the lack of long-term ecotoxicological studies conducted with nanoparticles. The aim of this study was to examine the long-term effects of uncoated silver nanoparticles (Ag NPs) and aqueous silver (AgNO<sub>3</sub>) added to sediment on survival, growth and reproduction of the sediment-dwelling polychaete *Capitella teleta*. *C. teleta* were exposed to three nominal concentrations (1 µg Ag/g dry weight sediment (dw sed), 10 µg Ag/g dw sed and 100 µg Ag/g dw sed) added to sediment as Ag NPs or AgNO<sub>3</sub> for a period of 11 weeks. Uptake kinetics and bioaccumulation of Ag in *C. teleta* were also studied. Effects at the individual level were extrapolated to predict potential population-level effects using a mechanistic effect model. The resulting model predictions and their applications for risk assessment will be discussed.

#### TH095

##### **Investigating effects of silver nanoparticles on the soil community - Concept of an outdoor TME study**

M. Hammers-Wirtz, A. Toschki, Research Institute gaeia

The production and use of silver nanoparticles (Ag-NP) have markedly increased in the recent years resulting in an increasing release of Ag-NP into the environment. The main entry of Ag-NP into the environment occurs via sewage sludge and thus the soil is the compartment receiving the highest load of Ag-NP compared to the aquatic environment. Nevertheless, most studies investigating the potential effects of Ag-NP focused on the aquatic environment, while investigations of effects on soil organisms are scarce. The few studies comprising soil organisms so far have been conducted with single species exposed to Ag-NP for a short-term period. However, there is a lack of knowledge how a complex soil community is affected by Ag-NP over a longer period of time. Ecotoxicological impacts on soil communities can be studied using Terrestrial Model Ecosystems (TME). This higher tier approach has been developed to investigate the impact of pesticides on the soil fauna under outdoor conditions over a time period of one year. It has been proven as a valid method to detect both effects on the community level as well as on the population level and to observe a potential recovery during the study period. In our study we will use the TME approach to investigate potential long-term effects of different Ag-NP on the soil community. Here we will focus on effects on collembolans and oribatid mites, two important groups among the mesofauna, as well as on the community of earthworms. In this poster the project targets, the study design and the conceptual approach of the investigations will be presented.

#### TH096

##### **Stochastic risk assessment of Ag nanoparticles for inhalation exposure route**

C. Pang, University CaFoscari Venice / Dept of Environmental Sciences Informatics and Statistics; D. Hristozov, Ca Foscari University of Venice; M. Tsang, US EPA ASPH Fellow / Office of Research and Development; A. Zabeo; E. Semenzin, Ca Foscari University of Venice / Department of Environmental Sciences Informatics and Statistics; A. Marcomini, University of Venice / Department of Environmental Sciences Informatics and Statistics

Silver nanoparticles (AgNPs) are a high-volume substance used in textiles, catalytic, optoelectronic, sensing and biotechnological applications because of their unique antibacterial, optical, electrical and thermal properties. With the increasing application of AgNPs in consumer and medical products, there are growing concerns about their health implications. Various studies had showed that AgNPs can migrate to liver, spleen, lungs, kidneys and brain and induce toxicity *in vivo*. These data demonstrated that reactive oxygen species, oxidative stress and modified inflammatory responses play an important role in *in vivo* toxicity. Although there is a lot of data on AgNPs toxicity the main shortcomings in the state of the art include a lack of longer-term inhalation studies essential for risk assessment (in most study bolus instillation was used as substitute for inhalation). In addition, mostly acute *in vitro* and *in vivo* data are available, while the use of such data to predict long-term risks is not recommended, as suitable material-specific uncertainty factors for exposure duration extrapolation are presently unavailable. Moreover, the pulmonary exposure route has been investigated significantly more than ingestion, which is another important route of exposure, especially in consumer settings. Therefore, we chose the inhalation exposure route to perform long-term health risk assessment of AgNPs. First, a literature review was conducted to collect the available toxicity data for AgNPs. Then, the Benchmark Dose (BMD) approach was applied to derive lower benchmark dose confidence limits (BMDLs) to be used as starting points in

estimating Derived No-Effect Levels (DNEL). The BMD method was adopted because it is considered statistically more powerful than the No Observable Adverse Effect Level (NOAEL) method. The last step of the study integrates the obtained DNELs' statistical distributions with predicted exposure concentrations' statistical distributions in order to evaluate the risk of AgNPs for inhalation exposure route in a stochastic framework. The proposed stochastic framework is meant to be useful in taking into account inherent uncertainties in the system while not trying to perform a full probabilistic assessment which would require much more data which is hardly collectable. The results from the application of this approach to the AgNPs case study will be presented.

#### TH097

##### **Chronic effects of CuO nanoparticles on *Lymnaea stagnalis*: implications for environmental risk assessment?**

N. Falk, Roskilde University / Department of Environmental Social and Spatial Change; J. Zwicky, Roskilde University / ENSPAC; J. Reventlow, Roskilde University / Department of Environmental Social and Spatial Change; S.F. Hansen, Technical University of Denmark DTU / DTU Environment; A. Palmqvist, T.B. Knudsen, Roskilde University / Department of Environmental Social and Spatial Change; A. Thit Jensen, F.R. Khan, Roskilde University / ENSPAC; K. Syberg, Roskilde University / Department of Environmental Social and Spatial Change

Engineered nanomaterials (ENMs) are increasingly used in a wide range of products due to their specific and advantageous properties. The rapid development within the field of ENMs, has resulted in a demand for regulatory reconsiderations. However, the regulation of ENMs is subject to a number of limitations, due to challenges regarding particle characterization, lack of test methods and specific guidelines resulting in incomparable scientific data. Further, current regulation is typically derived from acute toxicological data, thereby overlooking the possible chronic effects of ENMs on the environment and human health. In this study chronic effects of copper oxide nanoparticles (CuO NPs) on the freshwater pulmonate snail, *Lymnaea stagnalis* were assessed. Juvenile snails were exposed to 2.5, 5.5 and 12 µg Cu/L added as either CuO NPs or CuCl<sub>2</sub> in water for 56 days. Effects on survival, growth rate and reproductive output as well as bioaccumulation were measured. Potential delayed effects and the ability to recover from Cu exposure was further assessed by transferring half the snails to clean water after 28 days post exposure. CuO NPs were characterized by dynamic light scattering, zeta potential, dissolution and TEM. The results are discussed in a regulatory context with regard to the relevance of the existing regulation on ENMs. Focus is on the European chemical legislation REACH, and to which extent it is necessary for current methods of environmental risk assessment to encompass the unique properties and specific toxicological effects of nanoparticles.

#### TH098

##### **Comparative effect of silver nanoparticles and silver nanowires on the growth and photosynthetic activity of green alga *Chlorococcum infusionum***

S. Nam; Y. An, Konkuk University / Department of Environmental Science

Silver nanoparticles (AgNPs) are widely used in various products including medical equipment coatings, cosmetic products, textiles, sprays and other products. Silver nanowires (AgNWs) are used in nanoelectronic applications and solar cells. This study investigated the inhibitory effects of polyvinylpyrrolidone (pvp)-coated AgNPs and AgNWs using green alga *Chlorococcum infusionum*. *Chlorococcum infusionum* was cultured in Bold's basal medium (BBM) and exponentially growing strain was exposed to pvp-AgNPs and AgNWs for 72h. Growth and photosynthetic activity of *C. infusionum* was assessed after 72h. Growth inhibition was quantified from yield based on chlorophyll fluorescence, and inhibition of photosynthetic activity was assessed by OJIP chlorophyll fluorescence transient from photosystem II activity. After 72h, growth and photosynthetic activity of *C. infusionum* was significantly inhibited in both pvp- AgNPs and AgNWs. OJIP chlorophyll fluorescence transient from photosystem II activity remarkably declined with the elevated concentrations of pvp-coated AgNPs and AgNWs. Pvp-AgNPs showed higher inhibition against *C. infusionum* compared to AgNWs in both growth and photosynthetic activity. This study compares toxicity of pvp-AgNPs and AgNWs exposure on the green alga *C. infusionum*. This research was supported by Basic Science Research Program through the National Research Foundation of Korea (NRF) funded by the Ministry of Science, ICT and future Planning (2014R1A2A1A11050513).

#### TH099

##### **ENVIRONMENTAL RISK ASSESSMENT OF ALUMINA-BASED NANOMATERIALS. ECOTOXICITY AND BIODEGRADABILITY STUDY**

S. PEREZ CATAN, CNEA / Centro Atómico Bariloche; G. Svartz, UNSAM - CONICET / Instituto de Investigación e Ingeniería Ambiental y Escuela de Ciencia y Tecnología; M. Papa, INTI / INTI AMBIENTE; A. Soldati, CNEA - CONICET / Centro Atómico Bariloche; P. Samter, INTI / INTIQUIMICA; M. Jordán, INTI / INTI AMBIENTE; R. Peter Gauna, INTI / INTIQUIMICA; H. Troiani, CNEA - CONICET / Centro Atómico Bariloche; M.M. Guraya, CTP-CNEA / Centro Atómico Bariloche; C. Perez Coll, Universidad Nacional de San Martín

During last years there has been an upward trend in the use of manufactured Nanomaterials (NMs) in a variety of products, promoted by the increasing technology developments. The fate of the NMs released in the environment and the

subsequent impact on the ecosystems, have become, however, a matter of concern due to the potential toxicity of these materials. The environments are stochastic dynamic systems where engineered NMs could suffer biological interaction, physical and chemical changes, and eventually become an ecological risk. All these processes are very difficult to follow and predict due to the great deal of variables involved. Alumina nanoparticles are widely applied in sanitary sectors and many industrial processes and devices, as nanofiltration and nanoelectrodes, respectively. Some alumina based NPs have proved toxic in *in vitro* cell assays by oxidative stress signs, inflammatory response, and DNA damage among other cell injuries observed. NMs are best candidates for interdisciplinary research because their study involves very different areas in order to characterize their structure and understand their physicochemical behavior, toxicology, and potential environmental impact. We present the first results of a nano-ecotoxicological evaluation of alumina-based materials prepared in our laboratory, as Al-NMs and NiAl-NMs with NiO particles. NPs were characterized regarding structure by XRD, SEM, TEM, and surface area. Biochemical oxygen demand (BOD5) and toxicity standardized assays were also conducted. Bioassays with and without organic matter were previously carried on for Zeta potential and particle size determination. Surface areas of all materials were about 250 m<sup>2</sup>/g and Ni particles of 20-30 nm in size were determined for NiAl-NMs. BOD5 values decreased up to 40% with respect to those of control samples. The bioassay with luminous bacteria (*Vibrio fischeri*) MICROTOX test gave LC50= (39.39 ± 10.63) % for Al-NPs and LC50= (26.73 ± 5.32) % for Ni Al-NPs at 30 min exposure. Tests at 80 min exposure showed a decrease of those values of about 25 %. The lethal and sublethal effects of NMs on amphibian *Rhinella arenarum* larvae (Stage 25) assayed by means of the standardized AMPHITOX tests, showed LC50 = 0.8 mg / L and NOEC = 0.08 mg / L.

### TH100

#### Ecotoxicity of graphene-based materials on aeroterrestrial microalgae

A. Montagner, University of Trieste / Life Science; M. Bidussi, University of Trieste / Department of Life Sciences; S. Bosi, University of Trieste / Department of Chemistry; V. León Castellanos, E. Vázquez Fernández-Pacheco, University of Castilla La Mancha / Department of Química; M. Tretiaich, University of Trieste / Department of Life Sciences; M. Prato, University of Trieste / Department of Chemistry

The importance of graphene-based materials on every day life is currently exponentially rising and hence it is essential to understand the potential effects of this materials-family on living organisms, particularly on photoautotroph organisms, which are at the basis of the primary production of marine and terrestrial ecosystems. In the framework of the Graphene-Flagship project, WP2 "Health and Environment", we tested the ecotoxicity of two highly standardized types of graphene, few layers graphene (FLG) and graphene oxide (GO), on aeroterrestrial microalgae. Axenic cultures of seven species selected for their different ecology and growth-type were exposed at 0.01, 1, and 50 µg/ml in two ways: in the first one (D, deposited) the graphene suspension was filtered and let to dry out on acetate cellulose membranes, and afterwards an algal cells suspension in water was deposited above the layer of deposited graphene; in the second one (S, shaken), a suspension of algal cells and graphene was prepared, shaken for 30' and deposited on the membranes. Seven inoculated disks (one control plus three D and three S, treated at the three concentrations) were laid on solid BBM at the bottom of special vessels (n=9 per species) which allow gas exchange in sterile conditions. Vessels were kept at 21°C, 17 µmol photons m<sup>-2</sup> sec<sup>-1</sup>, 12/12 h light/dark photoperiod for 4 weeks, and afterwards membranes were cut in two: one half was used to measure the content of photosynthetic pigments (chlorophylls and total carotenoids), while the other half was used to measure the chlorophyll *a* fluorescence emission. The chlorophyll content can be used as a proxy to monitor algal colony growth and was measured spectrophotometrically in crude DMSO extracts. The Chl<sub>a</sub>F emission, namely the parameter F<sub>v</sub>/F<sub>m</sub>, is a proxy of photosystem efficiency and can detect physiological changes due to environmental stress. The photosynthetic pigment content showed a complex pattern of effects, with species-specific effects of treatments (D vs S) and graphene types (FLG vs GO). With respect to Chl<sub>a</sub>F emission, control values of F<sub>v</sub>/F<sub>m</sub> varied naturally amongst species but there were no significant differences amongst treatments and concentrations, although some differences between FLG and GO exposure were observed. Additional analyses are currently investigating the short-term effects of FLG and GO exposure on algal species in terms of K<sup>+</sup> release, and internalization phenomena.

### TH101

#### Nanotechnology in agriculture, feed and food: overview of marketed/in-development applications and regulatory aspects

S. Gottardo, Institute for Health and Consumer Protection Nanobiosciences Unit; K. Aschberger, European Commission - Joint Research Centre / Nanobiosciences Unit - Institute for Health and Consumer Protection; V. Amenta, European Commission Joint Research Centre / Institute for Health and Consumer Protection Nanobiosciences Unit; M. Arena, EFSA - European Food Safety Authority / Pesticides; H. Bouwmeester, RIKILT, Wageningen University; P. Brandhoff, RIKILT Wageningen UR; A. Mech, European Commission Joint Research Centre / Institute for Health and Consumer Protection Nanobiosciences Unit; H. Rauscher, European Commission - Joint Research Centre / Nanobiosciences; R. Schoonjans, M. Vettori, European Food Safety Authority; R. Peters, RIKILT / Contaminants Nanotechnology is applied in several industrial sectors including agriculture,

food/feed production and packaging. It is expected that these applications will increase in the near future and may therefore become a relevant source of release of nanomaterials (NM) into the environment. To gain more knowledge on this issue, RIKILT and the Joint Research Centre (JRC) have prepared for the European Food Safety Authority (EFSA) an inventory of already marketed and in-development applications of NM in agriculture, feed and food, and carried out a review of regulatory aspects concerning NM in both EU and non-EU countries. Both the inventory and the regulatory review are based on information collected through an extensive search of literature and webpages, complemented by questionnaires sent to different stakeholders (i.e. industry, research institutes, and competent authorities). An analysis of the information records in the inventory shows that nano-encapsulates, silver and titanium dioxide are the most encountered NM type and that food additive and food contact material are the most frequent application type. The use of NM in preparation/development of novel food, feed additives, and pesticides/biocides is mostly in the research and development stage. In EU, NM are explicitly covered by e.g. Regulation on the Provision of Food Information to Consumers (FIC Regulation 1169/2011), Regulation on Plastic Food Contact Materials and Articles (10/2011), and Regulation on Active and Intelligent Materials and Articles (450/2009). A legally binding definition is also provided in the FIC Regulation. Other pieces of legislation are currently under revision to better address NM, e.g. Novel Food Regulation (258/97) or Annexes to the REACH (Registration, Evaluation, Authorisation and Restriction of Chemicals) Regulation (1907/2006). Countries outside the EU have limited NM-specific legislation and no legally binding definition. They rather adopt a broader approach that builds mainly on guidance for industry. The presentation will summarise the contents of the inventory, identify the main trends in the current and reasonably foreseen use of nanotechnology in agriculture, feed and food, and discuss possible implications for the environment. The presentation will also investigate the differences in EU and non-EU legislation addressing NM in agriculture, feed and food.

### TH102

#### Risk assessment of solid lipid nanoparticles loading agrochemicals (fungicides and herbicides) aiming agriculture applications

E.V. Campos, Sao Paulo State University - UNESP / Engenharia Ambiental; J.L. Oliveira, São Paulo State University - UNESP; M. Pascoli, University of Sorocaba; T. Pasquoto, Universidade Federal de São Carlos; R.d. Lima, Uniso / Biotechnology; L.F. Fraceto, Sao Paulo State University - UNESP / Environmental Chemistry

Carbendazim (MBC) and tebuconazole (TBZ) are widely used in agriculture for the prevention and control of fungal diseases<sup>1</sup>. Atrazine (ATZ) and simazine (SMZ) are members of the triazines family and are used in the pre- and post-emergence control of weeds<sup>2</sup>. Solid lipid nanoparticles (SLN) are carrier systems that offer advantages including changes in the release profiles of bioactive compounds and their transfer to the site of action, reduced losses due to leaching or degradation, and decreased toxicity in the environment and humans. The aim of this study was to prepare and characterize nanoparticles and evaluate the cytotoxicity. SLN were prepared according to the method of water/oil emulsion and evaporation of the solvent<sup>3</sup>. To investigate the stability of nanoparticles formulations (with and without pesticides) some physico-chemical properties were determined such as: mean size diameter, polydispersivity, zeta potential and encapsulation efficiency during a period of 120 days. Cellular viability was determined using the reduction of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT). The number of viable cells (mouse fibroblast) was determined by measuring the amount of MTT converted to formazan (a purple compound) by the mitochondrial dehydrogenases<sup>4</sup>. Solid lipid nanoparticles with fungicides and herbicides presented good colloidal stability as function of the time. The results of cell viability assays showed that the SLN do not provoke a reduction in 3T3 cell viability. The exposure of the cells to the commercial formulations (fungicides or herbicides) showed a strong reduction in 3T3 cell viability (around 25 %) and when the herbicides or fungicides were loaded in SLN the observed cell viability was around 80 %. These results showed that the encapsulation of the pesticides in solid lipid nanoparticles decreases the cytotoxic effects of these chemicals in 3T3 cells and these nanopesticide formulations could be an interesting alternative to control the pests in agriculture and reduce the environmental impacts of non-target organisms. Acknowledgments: Fapesp, Fundunesp, CNPq and Capes.

### TH103

#### Influence of soil pH in the effects of ZnONPs on the antioxidant activities and Zn uptake in three plant species (*T. aestivum*, *R. sativus* and *Z. mays*)

C. Garcia-Gomez, INIA; A. Obrador, ETSI Agronomos (UPM); J.M. Alvarez, D. Gonzalez, ETSI Agronomos / Agricultural Chemistry; C. del Rio, INIA; M. Babin, INIA / Dpto. Environment; M.D. Fernández, INIA / Environment

In recent years, the study of phytotoxicity of NPs has made rapid progress, but important issues remain to be solved, among them, the role of soil and the importance of the physicochemical soil characteristics for their toxicity and accumulation potential. It is due to most available information about the NP toxicity in higher plants comes from studies on hydroponic media. Moreover, it is necessary to develop more sensitive and specific toxicity indicators based on biochemical changes for evaluating the toxicity of NPs. The ability to generate reactive oxygen species (ROS) has been identified as a possible mechanism of NP toxicity. ROS accumulation induces lipid peroxidation, membrane and DNA/RNA damage and

metabolism imbalance. Plants have evolved various protective mechanisms to limit oxidative damage caused by ROS accumulation such as the production of antioxidants (e.g. ascorbate, carotenoids or thiols) and antioxidant enzymes. The aims of this study were to study the influence of soil pH in ZnONP toxicity and accumulation to different plant species and to assist in the selection of potential biomarkers of soils contaminated with these nanoparticles. ZnONPs were selected because there is a growing interest in their use in agricultural formulations taking advantage of their properties as a UV blocker, or as fertilizers. The ZnO NP toxicity was tested in three plant species of agronomic interest: *Triticum aestivum*, *Rabanus sativus* and *Zea mays*. Two agricultural soils: an acid soil (pH 5.4) and a basic soil (pH 8.3) were spiked with 20, 225, 450 and 900 mg ZnO NP kg<sup>-1</sup> (Zn basis). The effects of the treated soils on ROS levels and the antioxidative defense system of plant species were analyzed after 35 days of exposure. Thus, the changes on the activity of the antioxidant enzymes (APX, GPOD and CAT), the levels of reduced glutathione and proteins, and the effects on lipid peroxidation were measured. To obtain a better understanding of the toxicology of ZnONPs, these effects were compared with visible damage at the functional level of the whole organism: seedling emergence and growth, and the changes in the chlorophyll levels. In addition, Zn concentration in roots and shoots of plant species were determined. This research was funded by the Spanish project RTA2013-00091-C02-01.

#### TH104

##### The Effect of Nano-ZnO Ecotoxicity on *P. subcapitata*

A. Erdem, Akdeniz University / Department of Environmental Engineering; M. Ozkaleli, Akdeniz University / Dept. of environmental engineering; C. Moral, Akdeniz University / Department of Environmental Engineering  
Nanoparticles (NPs) are the materials with at least two dimensions between 1 and 100 nm. Mostly these NPs are natural products but their tremendous commercial use has accelerated the artificial synthesis of engineered NPs (ENPs). The excessive production and usage of the ENPs have brought a new issue that how the environment has been affected. Therefore, detail understanding of their sources, release interaction with environment, and possible risk assessment should be provided to form a basis for safer use of ENPs with minimal or no hazardous impact on environment. However, there are still no specific standardized protocols or certified reference materials for the ENPs testing. Nevertheless, researchers are trying to find out the best methodologies to perform these kinds of evaluations. Moreover, the roles of ENPs in the inactivation mechanism of organisms and the properties of the ENPs affecting the ecotoxicity still remain unknown. EU commissions recommend for further studies on standardization of the methodologies and conducting experiments to assess the behavior and fate of the ENPs in real environmental conditions. In this study, through experimenting with different concentrations of ZnO NPs prepared with different dispersion methods in synthetic surface water samples with different water quality parameters on algae *P. subcapitata*, we have shown that cellular membranes were significantly compromised under ambient light radiation and nano-ZnO concentrations, and even under absence of light. Our results suggest that adverse effects are not necessarily only attributable to individual particles smaller than 100 nm but also to low concentrations of larger, naturally agglomerating ZnO NPs. Cell membrane damage was more pronounced in experimental setups including irradiated ZnO NPs, due to photocatalytic activity of the ENPs. The generation of malondialdehyde (MDA) further suggests nano-ZnO-induced affects the cellular membrane. The endpoints are also shown in EC50 and LC50 of the communities, and in microscopy images. Our findings indicate a high sensitivity of algal communities to levels of ENPs concentration that are to be expected in the surface water environment. However, to understand the long-term effect of ENPs on the ecosystem, substantial information is required regarding their persistence and bioaccumulation. The authors would like to acknowledge the financial support from Akdeniz University (AU-BAP Project No 2013.01.0102.010).

##### Human toxicity testing strategy towards development for grouping of nanomaterials

N.M. Deleebeeck, Arcadis Belgium / Environment; M. Messiaen, Arcadis Belgium nv; E.A. Bleeker, RIVM; D.T. Sijm, Head Bureau REACH; F. Van Broekhuizen, National Institute for Public Health and the Environment; K. Selles, Ecotox Services Australasia (ESA) laboratory  
The use of nanomaterials in manufacturing operations and consumer products has increased as scientists and engineers have realized their benefits. The physicochemical characteristics of nanomaterials may differ from their non-nano counterparts, affecting fundamental properties as solubility, reactivity, environmental transport, and toxicokinetics. This may introduce risks for humans or the environment. This study explores the physicochemical properties of nanomaterials and their potential impact on toxicity, kinetics, and exposure in order to come to a strategy towards the development of concepts and criteria for grouping of nanomaterials for the purpose of testing for nanomaterial hazards and determination of potential risks. The proposed testing strategy involves four steps. In a first step, the known information is compiled, including information on potential read-across candidates. Based on this information a hypothesis is developed (step 2) and assessed to determine whether and how a nanomaterial might exhibit unique behaviour under relevant time scales and conditions. To test the hypothesis (step 3) to what extent grouping can be used, a tiered strategy is

proposed. In the first tier, physico-chemical data, like chemical composition, surface characteristics (coating, capping agents, functionalization), impurities and particle size are so essential to characterise a nanomaterial that they should always be collected. Other data (e.g. shape, porosity), may be appropriate to better understand the potential for exposure. In the second tier, *in vitro* dissolution/bioaccessibility testing or *in vitro* reactivity studies to support human health endpoints may be considered. In the last tier, the test strategy may incorporate toxicity testing and/or *in vivo* toxicokinetic testing to support read-across. From the data collected in the tiers, it can be assessed (step 4) if the nanomaterial has a unique behaviour or not. All the data can be used in a weight-of-evidence approach to support the grouping hypothesis. This exercise was done for the following endpoints: acute toxicity, skin/eye irritation, sensitization, mutagenicity, repeated dose toxicity and carcinogenicity. Silver and titanium dioxide nanoparticles were worked out as test cases.

#### TH106

##### Effects of Nanoparticles on Skin Irritation and Corrosion Using 3D Human Skin model

K. Park, H. Kim, H. Lee, J. Choi, Dongduk Womens University / College of Pharmacy  
Effects of nanoparticles including silver (AgNP), titanium oxide (TiNP), aluminum oxide (AlNP) or iron (FeNP) on skin corrosion and irritation were investigated by using *in vitro* 3D human skin model, Epiderm(TM). Skin models were incubated with nanoparticles for a definite time period and cell viability was measured by MTT method. Skin corrosion was identified by the decreased viability based on the pre-determined threshold, which was 50% after 3 minutes exposure and 5% after 60 minutes exposure. Skin irritation was identified by decreased viability to 50% by 60 minutes exposure and 42 hr post-incubation after washing the test material. In the corrosion test, the viability of Epiderm(TM) treated with positive chemical (8N KOH) for 3 minutes was 92%. However, the viability for 3-min exposure was 89% in AgNP-treated Epiderm(TM), 96% in TiNP-treated, 91% in AlNP-treated, and 88% FeNP-treated group, which is over the threshold level. In case of 60 min exposure, viabilities were also over threshold level in all the nanoparticles treated groups. In the irritation test, Epiderm(TM) models were exposed to positive control of 5% SDS for 60 minutes and viability was measured after 42 hr post-incubation without test materials. The viabilities of Epiderm(TM) were over the threshold level in all the nanoparticle treated groups. IL-1 $\alpha$  release and histopathological findings support the results of cell viability test. This result provides the evidence that AgNPs, TiNPs, AlNPs and FeNPs are 'non-corrosive' and 'non-irritation' to the human skin by a globally harmonized classification system.

#### TH107

##### Screening risk assessment of nano-enabled products used in restoration of works of art

E. Semenzin, Ca Foscari University of Venice / Department of Environmental Sciences Informatics and Statistics; C. Pang, University CaFoscari Venice / Dept of Environmental Sciences Informatics and Statistics; A. Brunelli, Environmental Sciences Informatics and Statistics; D. Hristozov, Ca Foscari University of Venice; T. Balbi, University of Genova / DISTAV; L. Canesi, university of genoa / DISTAV; D. Chelazzi, University of Florence; A. Marcomini, University of Venice / Department of Environmental Sciences Informatics and Statistics  
Traditional restoration methods and conventional materials often lack the necessary compatibility with the original works of art and a durable performance. To address these issues, the FP7 Project NANOFORART (Nano-materials for the conservation and preservation of movable and immovable artworks) has focused on the development of manageable methodologies, based on advanced materials with a low environmental impact, namely nanoparticles dispersions, micellar solutions, microemulsions and chemical gels, to be used for the consolidation, pH control and cleaning of works of art. Environmental impacts of a set of nanoparticles dispersions (i.e. four Ca(OH)<sub>2</sub> nanoparticles dispersions in 1-propanol, 2-propanol, ethanol, and two CaCO<sub>3</sub> nanoparticle dispersions in water and in a 2-propanol/water mixture) were assessed along their life-cycle by performing a screening risk assessment. Exposure to both humans and the environment was evaluated by estimating the potential nanoparticles release in manufacturing/preparation, application and post-application stages, thus identifying relevant exposure scenarios. Health and environmental hazards were evaluated by self-classifying the investigated formulations according to the "Guidance on the Application of the CLP Criteria" provided by European Chemicals Agency (ECHA), supported by tests on nanoparticle dispersions performed according to Human Skin Equivalent Models. The results revealed that no relevant exposure and effect can be expected for the environmental compartments. For human health, although the self-classification highlighted potential health hazards for some of the proposed systems, the main route of exposure, represented by dermal contact, could lead to adverse toxicological effects only for one system at the highest tested concentration (representative of real application conditions). All the other systems resulted as not irritant for human skin at concentrations representative of real application conditions. However, the use of common personal protective equipment (i.e. gloves, glasses) and prevention measures (i.e. ventilated room), is always recommended in order to assure a complete protection of workers from any potential adverse effects. This is one of the first studies addressing environmental impacts of nano-enabled products that can be

employed for cultural heritage applications, to substitute the use of pure organic solvents and other chemicals with recognized toxicity and environmental impact.

#### TH108

##### **Conceptual framework for Sustainable Nanotechnologies Decision Support System (SUNDS)**

**Keywords:** Sustainable Nanotechnology, Decision Support, Multi Criteria Decision Analysis Application of methods like Life Cycle Assessment (LCA) and Risk Analysis (RA) to Engineered Nanomaterials (ENM) are challenging because of knowledge and data gaps, and can impede safe and sustainable nanomanufacturing. While LCA has great utility for quantitative impact evaluation and regulatory and industrial decision making, lack of nanomaterial-specific characterization factors and reliable Lifecycle Inventory data. Multi-Criteria Decision Analysis (MCDA) can be used to integrate RA and LCA within a framework for Sustainable Nanotechnology that can also incorporate stakeholder values and estimate uncertainty. The European Commission has funded a project on sustainable nanotechnology (SUN, <http://www.sun-fp7.eu/>) that aims to build tools to assess ecological and human health risks, environmental impacts, risk management measures and benefits of nanoproducts. These tools will be integrated within an overarching decision framework and support tool for Sustainable Nanotechnology to support the selection of risk management alternatives (e.g. safety by design technological alternatives, personal protective equipment). The SUN Decision Support System (SUNDS) is currently in development in the SUN project through a process of integrating SUN tools with user needs. The framework will be implemented in a user-friendly modular software and will be tested on the SUN case studies. We present SUNDS conceptual framework and user needs (industry, regulatory and insurance sector) with respect to SUNDS features.

#### TH109

##### **The GUIDEnano strategy for nanomaterial environmental hazard assessment along the life cycle**

G. Janer, Acondicionamiento Tarrasense; M. Diez-Ortiz, Leitat Technological Center; M. Fernandez-Cruz, INIA - National Institute for Agricultural and Food Research and Technology / Environment; D. Hernandez-Moreno, INIA / Environment; J. Izquierdo, INIA; D. Spurgeon, Centre for Ecology & Hydrology; M. Park, RIVM; N. Ferraz, University of Uppsala; J. Catalán, Finnish Institute of Occupational Health; S. Vázquez-Campos, Safety Sustainability; C. Svendsen, CEH, Wallingford / Pollution and Ecotoxicology  
GUIDEnano aims at developing an interactive web-based Guidance Tool to support the risk assessment and risk management of a nano-enabled product. A first step will be to assess the possibility to use existing hazard assessments for similar materials, by assessing similarity between the exposure-relevant and the already tested NMs. This will be done by using a set of predefined read-across criteria, such as chemical composition, degradation/dissolution rate, shape, primary size and aggregated size, charge, and different coating properties. The consideration of all these read-across criteria leads to a similarity score for each physicochemical property evaluated. To determine the ultimate similarity score between two NMs, the lowest similarity score is selected. As a second step, in cases where the exposure-relevant material is not sufficiently similar to any of the previously assessed materials, the Tool would base the hazard assessment on individual studies available for the NM of interest. Each individual study, providing it is relevant for the environmental compartment of interest, would be evaluated for two aspects: its reliability and the similarity of the tested NM to the exposure relevant NM (i.e., the read-across process). Within the reliability concept, we include the combination of the Klimisch score and a specific nano score that accounts for the nanomaterial characterization details included in the study. A minimum score for these two aspects will be needed to use such test data for the derivation of the final PNEC value and, in such cases, the score will also inform on the uncertainty around it. A third and final step, in cases where no relevant test information would be available for a nanomaterial, we consider the use of general categories of nanomaterials and associated default hazard values. There is so far little evidence of direct physical effects of NMs in the environment, and the vast majority of data suggests that observed toxicity can be explained by toxicity from the component materials. Hence, we consider that, with the current state of knowledge, an expectedly

conservative default value for a PNEC would be based on the toxicity of the NMs component materials.

#### TH110

##### **Ecosafety of nanomaterials for seawater remediation**

E. Bocci, University of Siena / Environmental Sciences; S. Buono, Università degli studi di Napoli Federico II; C. Gambardella, ISMAR-CNR; V. Vitiello, ISPRA Italian Institute for Environmental Protection and Research; M. Vannuccini, University of Siena / Physical earth and environmental science; e. bergami, University of Siena / Physical Earth and Environmental Sciences; F. Freyria, Massachusetts Institute of Technology / Department of Chemistry; S. Esposito, University of Cassino and Lazio Meridionale / Department of Civil and Mechanical Engineering; M. Massa, Centre of Food Innovation and Development in the Food Industry (CAISIAL); B. Bonelli, Politecnico di Torino / Dipartimento di Scienza dei Materiali e Ingegneria Chimica; M. Faimali, CNRIstitute of Marine Science ISMAR; i. buttino, ISPRA / Ecotoxicology and plankton biology Lab; I. Corsi, University of Siena / Physical Earth and Environmental Sciences  
The use of nanomaterials (NMs) for *in situ* remediation referred as nanoremediation represents a promising and cutting-edge solution, by ensuring a quick and efficient pollutants removal. However, their use should not pose any additional risk for the environment and natural ecosystems. The aim of the present study done in the framework of the NanoRemEco research project is to validate and define ecotoxicological tools to plan and realize *ecosafe* remediation techniques in the marine environment based on the use of *eco-friendly* NMs. The study has been organized using ecotoxicological bioassays in selected marine organisms belonging to different trophic levels. Two different n-TiO<sub>2</sub> formulation as Areoxide® Degussa P-25 (P25), the most used commercial titania, and newly synthesized pure mesoporous titania (MT) intended for sea water remediation have been tested alone and in combination with Cadmium (Cd), as model toxic marine contaminant to be remediated. Neither lethal nor sublethal toxicity was observed for single P25 and MT exposure in both brine shrimp and sea urchin, nevertheless when combined with Cd, a significant increase in toxicity was observed in sea urchin exposed to P25 respect to MT. The different behavior of P25 and MT in natural seawater (NSW) might affect their interaction with Cd and consequently toxicity; P25 tend to form bigger aggregates compared to MT and they significantly increase in presence of Cd perhaps affecting its bioavailability. Such preliminary data stress the need to deeply investigate NMs behaviour in sea water before any *in situ* environmental application as nanoremediation since this might affect bioavailability and toxicity of contaminants to be remediated. More important there is an urgent need to develop an ecosafety testing strategy for NMs used in sea water remediation in order to prevent any adverse impact to marine biota.

#### TH111

##### **A Quantitative Toxicogenomics Assay for High-throughput and Mechanistic Genotoxicity Assessment of Environmental Pollutants**

J. Lan, Civil Environmental Engineering; N. Gou, Northeastern University / Civil and Environmental Engineering; S.M. Rahman, Northeastern University / Civil Environmental Engineering; C. Gao, Northeastern University / Bioengineering; A. Gu, Department of Civil & Env Engineering / Department of Civil Env Engineering Biotechnology Initiative Program  
The ecological and health concern of mutagenicity and carcinogenicity potentially associated with an overwhelmingly large and ever-increasing number of chemicals and materials demands for cost-effective and feasible method for genotoxicity screening and risk assessments. In this study, we developed a DNA damage repair pathways-based quantitative toxicogenomics assay, using GFP-tagged yeast whole-cell array for *in vitro* genotoxicity assessment. The genotoxicity assay array consists of 38 selected biomarkers indicative of all the seven known DNA damage repair pathways and yields high-dimensional temporal altered expression profile in exposure to a chemical within 2 hrs. The assay was applied to assess four model genotoxic chemicals, three environmental pollutants and four negative controls across six concentrations, as well as four nanomaterials across three concentrations. Quantitative molecular genotoxicity endpoints were derived based on dose response modeling of a newly developed integrated molecular effect quantifier, Protein Effect Level Index (PELI). The molecular genotoxicity endpoints were found to correlate well with the conventional genotoxicity comet assay results in human lung epithelial cells (A549). To further evaluate the proposed genotoxicity assay, the genotoxicity endpoints (positive versus negative) and DNA damaging mechanisms revealed by our assay were compared and showed consistent results with multiple conventional *in vitro* as well as *in vivo* genotoxicity and carcinogenicity assays. The results suggested the conserved DNA damage repair strategies and pathways among different species and also provided promising evidence for the concept of adverse outcome pathways, to link the molecular initiating events to adverse outcomes at a biological relevant level. In addition, the high-resolution DNA damaging repair pathway alternated protein expression profiles allowed for chemical clustering and classification. This

toxicogenomics-based assay presents a promising alternative for fast, efficient and mechanistic genotoxicity screening and assessment of drugs, foods, chemicals, nanomaterials and environmental contaminants.

#### TH112

##### **Colon carcinogenicity assessment of water and effluents under the influence of textile activities**

F.H. Fernandes, UNIVERSIDADE ESTADUAL PAULISTA - UNESP / Pathology; G.d. Umbuzeiro, FACULTY OF TECHNOLOGY - UNICAMP / LEAL; M.O. Nasciutti, A.L. Sávio, C.C. Munari, B. Anfilo, Universidade Estadual Paulista UNESP / Pathology; D.F. Salvadori, Unesp

Azo dyes belong to a large family of synthetic dyes that are highly resistant to natural degradation. They are widely used in the textile industry and can reach the aquatic environment. We evaluated the potential of samples collected at two sites of two both under the influence of textile discharges to induce colon carcinogenicity in rats. Samples were collected during a severe drought condition (February, 2014), (i) at Quilombo River (QR) and (ii) and the treated effluent of Carioba Wastewater Treatment Plant (WWTP), Americana, State of Sao Paulo, Brazil. Rats (12 per group) were daily treated with *ad libitum* QR and WWTP treated effluent samples at 0.1, 1.0 and 10.0 % concentration by drinking water during two weeks. Animals treated with ethylenediamine tetra acetic acid (EDTA, 1.85 mg/kg body weight) and with 1.2-dimethylhydrazine (DMH, 160 mg/kg b.w.) administered by subcutaneous injection twice a week for two weeks were used as negative and positive controls, respectively. After six weeks of treatment, animals were euthanized (protocol approved by the Bioethics Committee, nº 1002/2013) and colon collected. Anatomical features (hearth, kidney and liver weight) were also assessed. One-hundred sequential fields from proximal, medial and distal colon were analyzed for the frequency of aberrant crypt foci (ACF). Liver hypertrophy was observed in rats treated with both WWTP and QR samples. Increased frequency of ACF in the proximal colon was detected in those animals treated with WWTP at the two highest doses (1 and 10%;  $p < 0.05$ ). In conclusion, data suggest the presence of potential carcinogens in Quilombo river and WWTP treated effluent samples.

#### TH113

##### **Chemical characterization and toxicological evaluation of airborne PM<sub>10</sub>, PM<sub>2.5</sub>, and PM<sub>1</sub> near cement plants**

N. Roig, Universitat Rovira i Virgili; F. Sánchez Soberón, Universitat Rovira i Virgili / Chemical Engineering; J. Rovira, Departament d Enginyeria Química; M. Mari, Rovira i Virgili University / Chemical Engineering; J. Sierra, Universitat Rovira i Virgili / Soil Science Unit; E. Martí, Universitat de Barcelona / Productes Naturals Biologia Vegetal i Edafologia; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering  
Urban particulate air pollution has a major impact on the quality of life and human health. There is a special concern over the amount of suspended fine and ultrafine particulate matter in urban areas. The breathable fraction of ambient particulate matter (PM) is often referred to as PM<sub>10</sub>. However, fine particulate matter (PM<sub>2.5</sub> and PM<sub>1</sub>) are able to go deeper in lung and alveoli, being related to cardiovascular disease, pulmonary disease, and cancer. Due to its adverse impact on human health, ambient fine particulate matter (PM<sub>2.5</sub>) is among the atmospheric pollutants subject to environmental regulation, particularly in the European Union. Pollutant mixtures may pose important adverse health effects, not only because of the effects of individual substances, but also as a result of the potential synergisms/antagonisms among them. Despite that, and because of the difficulties to assess the potential hazard of these mixtures, regulation measures to control the levels of pollutants are traditionally focused on the simple determination of individual contaminants in air. The objectives of this study are to characterize the size, morphology and chemical composition of the atmospheric particles (PM<sub>10</sub>, PM<sub>2.5</sub> and PM<sub>1</sub>) in two areas (urban and rural) located close to a cement plant. Their potential of ecotoxicity, cytotoxicity and genotoxicity for the human health is also determined. Samples of PM<sub>10</sub>, PM<sub>2.5</sub> and PM<sub>1</sub> fractions were collected with high-volume active sampling devices, and the contents of mineral matter, trace elements, C, TOC, N, S and soluble salts were analysed in the three different particles fractions. The size, morphology and composition of particles were also observed by means of Environmental Scanning Electron Microscope techniques, in order to observe differences between different PM fractions. The levels of ecotoxicity were evaluated by using the photo-luminescent bacteria *Vibrio fischeri*, while the potential of toxicity and genotoxicity was assessed by conducting the MTT and Comet Assays, respectively, both of them using on human lung epithelial cells A549 as target cells. The results show that Microtox is an excellent screening test to perform a first evaluation of air quality. In addition, A549 line cells allowed to distinguish when air samples are toxic and/or probable carcinogens for cell lungs.

##### **Electrophile-peptide adductome - Relationship with site- and mechanism-specific reactivity**

C. Slawik, Helmholtz centre for environmental research - UFZ / Ecological chemistry; C. Rickmeyer, Ilmenau University of Technology; S. Hirth, Martin-Luther-University Halle Wittenberg / Institute of Chemistry Food

Chemistry and Environmental Chemistry; A. Böhme, UFZ - Helmholtz Centre for Environmental Research / Ecological chemistry; G. Schuurmann, Helmholtz centre for environmental research - UFZ / Department of Ecological Chemistry  
For unraveling mechanistic causes of disease formation, the exposome defined as cumulative totality of exposure in the organism contains pertinent information.<sup>1</sup> Importantly, this internal chemistry is affected not only through the uptake of exogenous compounds, but also by the endogenous generation of substances in response to external stress, with electrophilic aldehydes generated from lipid peroxidation forming one prominent example.<sup>2</sup> Because electrophiles are ready to react with nucleophilic sites of peptides, proteins and the DNA, the respective adduct formation contributes significantly to the adductome as part of the exposome.<sup>3</sup> In the presentation, we compare peptide adducts of organic electrophiles as determined through LC/MS-MS with their mechanism- and site-specific reactivities, the latter of which are quantified through kinetic chemoassays<sup>4-6</sup> employing mono- and bifunctional model nucleophiles. The discussion includes the scope of electrophilic reactivity profiling for predicting electrophile-protein adductome patterns, taking into account opportunities for calculating the latter from molecular structure.<sup>7</sup> [1] Rappaport SM, Smith MT 2010. ##### **Determination of six parabens and four paraben derivatives in pharmaceuticals**

C. Moreta, Analytical Chemistry; M. Tena, University of La Rioja / Analytical Chemistry; K. Kannan, New York State Department of Health / Wadsworth Center Department of Health

Parabens are alkyl esters of 4-hydroxybenzoic acid (4-HB). Parabens are widely used as preservatives in cosmetics, foodstuffs and pharmaceuticals because of their low cost, high water solubility and broad spectrum antimicrobial properties. However, parabens have been shown to be weakly estrogenic in laboratory animal studies and hence, they are a group of endocrine disrupting compounds (EDCs). Human exposure to parabens is a concern and sources of human exposure are not well characterized. In this study, a method was developed to determine six most frequently used parabens and four paraben derivatives (methyl and ethyl protocatechuates, and mono and di- hydroxybenzoic acids) in pharmaceuticals. This method was based on solid-liquid extraction (SLE) and high performance liquid chromatography (HPLC) coupled to a triple quadrupole mass spectrometry detector (QQ-MS/MS). To our knowledge, this is the first comprehensive report of occurrence of parabens in pharmaceuticals. The method was applied for the analysis of more than 100 pharmaceuticals including liquid/syrup, cream, solid, prescription or over-the counter (OTC) drugs from the USA and a few other countries. Although a majority of the drug samples did not have parabens, levels up to 2 mg/g were found in some samples, being methylparaben followed by propylparaben the most abundant of them. Among paraben derivatives, 4-HB was predominantly found. Hydrolysis of parabens is an explanation for the presence of 4-HB in drugs.

#### TH116

##### **Online SPE LC-MS/MS method for the determination of hydroxylated polychlorinated biphenyls (OH-PCBs) in human plasma**

N. Quinete, Medical Faculty, RWTH Aachen University / Institute for Occupational and Social Medicine; T. Kraus, C. Aretz, T. Schettgen, RWTH Aachen University / Institute for Occupational and Social Medicine  
Over the last decade attention has been drawn to the metabolites of PCBs and their potential adverse effects in humans and wildlife. Hydroxylated polychlorinated biphenyls metabolites (OH-PCBs) have been shown to be strongly retained in human blood causing endocrine-related toxicity, particularly on the thyroid system. Traditionally, analytical methods for the determination of OH-PCBs require in general extensive sample preparation, which include a series of time consuming and low throughput liquid-liquid extraction and back extractions, evaporations, several steps of cleanup and, in some cases, derivatization prior the analysis by gas or liquid chromatography-mass spectrometry (GC-MS or LC-MS). The present study developed and validated a novel, sensitive and selective online solid phase extraction (SPE) method coupled to LC-tandem mass spectrometry (LC-MS/MS) for the separation and quantitation of 19 relevant congeners of OH-PCBs in human plasma. The developed method required minimal sample preparation and solvent consumption while improving throughput, detection and response in biomedical and/or environmental analysis. Limits of quantification (LOQ) ranged from 0.02 to

0.5 ng mL<sup>-1</sup> and extraction recoveries from 71-134% for all congeners. Intra- and inter-assay coefficients of variation were between 3.8 and 15 %. In order to evaluate the applicability of the method, a preliminary evaluation (N=90) was conducted in plasma from occupationally exposed workers of a transformer recycling plant and residents exposed to very high levels of PCBs in a German cohort. High chlorinated (penta- through hepta-chlorinated) OH-PCBs were the predominant congeners in human blood with concentrations up to 44.2 ng mL<sup>-1</sup>. Lower chlorinated OH-PCBs were occasionally detected, although mono-chlorinated OH-PCB congener was not present in any of the samples. Unknown OH-PCB congener peaks were also frequently present in the samples at relatively high concentrations, highlighting the need for the development of new standards. In addition, the relationship and associations between OH-PCB metabolites and their parent compounds in the studied cohort were also assessed.

#### TH117

##### **Targeted and Non-targeted Analysis of Phthalate Metabolite in Human Urine with Liquid Chromatography Mass Spectrometry: Identification and Occurrence for Exposure Assessment**

Y. Feng, C. Yao, Health Canada; P. Chan, McGill University

Phthalate esters are ubiquitous in our living environment due to their widespread use. The human exposure represents the totality of the chemical exposures over the course of an individual's lifetime. It is a challenge to assess human exposure to chemicals like phthalates through direct measurements of environmental contamination levels since they may not reflect actual exposure in an individual. As a result, a more accurate assessment of the exposure of the population to phthalates has been attempted by a combination of measuring specific metabolites of the phthalates in urine or other biological samples and information on the sources of phthalates, bioavailability and metabolism pathways in humans. In this study, we show the use of liquid chromatography triple quadrupole mass spectrometry (LC-MS/MS) and liquid chromatography quadrupole time-of-flight mass spectrometry (LC-QTOF) in analysis of targeted metabolites and non-targeted screening and identification of unknown phthalate metabolites in human urine. The precursor ion scan technique in triple quadrupole mass spectrometry was used to screen any molecule that can produce a product ion, m/z 121. Phthalate metabolites have a common product ion [C<sub>6</sub>H<sub>5</sub>COO]<sup>-</sup> which is represented as m/z 121 in the mass spectrum. Subsequently, the quadrupole time-of-flight mass spectrometry, which is high resolution mass spectrometry (HRMS), was utilized to elucidate structural information of the peaks observed in the precursor ion scan. The high mass accuracy and exceptional tolerance for sample complexity inherent to HRMS instruments allows distinguishing of analyte ions and product ions from interferences with similar mass and identification of unknown metabolites at trace levels. A core-shell column was used to further enhance the specificity of identification for non-targeted metabolites through improving the separation efficiency on the column prior to mass spectrometry. Canadian male urine samples in two groups, control and infertile, were subjected to a non-targeted analysis to identify any new or unmonitored phthalate metabolites of potential concern using a combination of LC-MS/MS and LC-QTOF. Targeted analysis was undertaken only using LC-MS/MS. This technique provides superior separation capabilities, fast screening of phthalate metabolites and accurate identification of unknown metabolites.

#### TH118

##### **Influence of socio-demographic and diet determinants on the levels of mercury in preschool children from a Mediterranean island.**

M. Garí, IDAEA-CSIC / Environmental Chemistry; J.O. Grimalt, Environmental Chemistry; M. Torrent, Àrea de Salut de Menorca IB-Salut. Fundació Caubet-CIMERA; J. Sunyer, Centre for Research in Environmental Epidemiology Mercury is well known as a major persistent pollutant. It can cause severe neurological damage to children. Humans are exposed to mercury basically through fish consumption. This study focuses on the presence of mercury in the infant population of Menorca, in the Western Mediterranean area, whose inhabitants are usual fish and seafood eaters. The research is based on 302 hair samples of four-year old children from the Menorca island collected within the INMA study. Determination of total mercury (THg) in hair was performed using inductively coupled plasma mass spectrometry (ICP-MS). Children from Menorca island show detectable levels of mercury in hair, with a mean concentration of 1.4 µg/g (ranging between 0.040 µg/g and 10 µg/g). 20% of the samples were above the WHO recommended value (2 µg/g in human hair). The concentrations in Menorca are rather high when compared with other populations, yet concur with the high levels of island populations, and certainly lower than in highly-exposed areas. The consumption of fish and seafood is clearly the leading factor explaining the degree of accumulation of mercury found. It is also the single most important factor, as it explains 15% of all the variability, whereas the rest of the factors studied represent, all together, only 5%. Oily fish is the main source of this pollutant, yet intakes of other types of fish and seafood, including squid and shellfish, which are frequent resources in Menorca island, also contribute to the body burden of mercury. Spain is in general a highly fish-consumer country. The population of the Menorca island has easy access to local fish and probably higher consumption level, making the levels of mercury in the Menorca population higher than in other Spanish locations (e.g. Tarragona or Granada). This research confirms that the greatest source of mercury for humans is the fish and seafood consumption, thus endorsing the

importance of the most recent international agreement on mercury, namely the Minamata Convention on Mercury, which was just adopted in January 2013 to prevent emissions and releases of this compound. The present study has not observed any association between mercury concentrations and adverse neurodevelopmental outcomes in the studied children. This anyway concurs with existing research, which only shows clear association among these two variables when the levels of exposure to mercury are severe, such as in heavily polluted locations.

##### **Human exposure to PAHs bound to PM fractions in an area influenced by a cement plant. PBPK application and risk assessment**

F. Sánchez Soberón, Universitat Rovira i Virgili / Chemical Engineering; M. Mari, Rovira i Virgili University / Chemical Engineering; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering; J. Rovira, Departament d'Enginyeria Química; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health; V. Kumar, Universitat Rovira i Virgili / Chemical engineering department; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health

Cement production is an energy intensive process that requires huge amounts of materials and energy. As a consequence of the combustion performed inside a cement kiln, a number of pollutants may be generated and released to air, being polycyclic aromatic hydrocarbons (PAHs) one of the most typical families of chemicals. PAHs form a varied group of chemical compounds structurally characterized by owing several aromatic rings. In the atmosphere, they can be found as vapor or linked to air particulate matter (PM). Inhalation is the main direct pathway of exposure to PAHs. Once inside the human body, PAHs may act as carcinogenic precursors, as well as being able to generate pulmonary, gastrointestinal and renal diseases. So far, gaseous PAHs have been more extensively studied. However, greater attention is being paid nowadays in elucidating the occurrence of particle-bound PAHs, since persistence and toxicity could be higher. Although it has been reported that PM bound to PAHs are usually associated to particles smaller than 1-2 µm, studies analyzing PAHs contained into this fraction are still sparse. Moreover, there is no much information about PAHs in areas influenced by cement plants, since information has been restricted to other chemicals, such as dioxins and furans, heavy metals and inorganic gases. Furthermore, the subsequent adverse health effects for the population living in the vicinity of these facilities is being subject of study. This study is aimed at understand better the distribution of PM-bound PAHs in an area under the direct influence of the emissions of a cement plant. Three PM fractions (10, 2.5 and 1 µm) were sampled with high volume active samplers in sites located near a cement factory in Catalonia (Spain). Filters obtained from the sampling were later analyzed by means of HRGC/HRMS to elucidate the PAHs content. In order to estimate the PAH exposure, a human respiratory tract model linked to a physiologically based pharmacokinetic model (PBPK) was used. Subsequently, human health risks were assessed, highlighting the risk of cancer associated to the inhalation of PAHs. The results of our study will help understand the distribution, target organs and health risks of different PAHs among different fractions of PM in an area influenced by the emissions of a cement factory. Hence, information might be applied to areas locally impacted by other industries which potentially emit PAHs to air, such as oil refineries

#### TH120

##### **Development of a personal exposure model based on Agent Based Modelling**

D.A. Sarigiannis, E. Handakas, D. Chapizanis, S. Karakitsios, Aristotle University of Thessaloniki / Chemical Engineering

This study aims to develop an individual and a population-level exposure model, integrating space-time activity data and air pollution levels in urban centres. The series of data that support this model are derived by i) personal sensors and ii) indoor and outdoor concentration data of particulate matter at various aerodynamic diameters (PM<sub>10</sub>, PM<sub>2.5</sub> and PM<sub>1</sub>), measured in Thessaloniki, Greece. Personal sensors (smartphones including GPS, accelerometer, thermometer and luminance sensors) have been used to capture personal data such as location, motion and intensity of activity. These data were used as input to an Artificial Neural Network model, aiming at deriving an individual time-activity model based solely on sensor data. Extrapolation to populations including various several age groups was done by using geographically explicit agent-based modeling (ABM) enabling thus a better understanding of the behaviour of individuals and populations in evolutionary settings. Personal activity data were analysed and then stored at the individual "agent" level. Using GIS and Agent-based Modelling Architecture (GAMA), the activity of the agent was projected on a GIS layer, superposed onto urban air quality maps. The population uptake of different PM size fractions was further investigated using a human respiratory tract (HRT) deposition model. PM levels and size distribution varied among the different seasons and parts of the urban agglomeration, as well as among different micro-environments and transportation means. Based on movement and activity, changes in exposure levels were calculated not only for the overall agent population but for individual agents as well. By estimating the daily time-activity patterns (as predicted by the coupled sensors-ANN-ABM platform) of vulnerable subgroups such as children or the elderly, we were able to estimate their personal exposure and uptake profile, taking into account a) PM size distribution across the different locations encountered and

b) differences in activity intensity. Overall, exposure to PM and especially deposition across the HRT are higher for children, as a result of the higher fraction time spent outdoors and in transport, the higher bodyweight-normalised inhalation rate, the more intensive overall activity and age-dependent differences in respiratory physiology.

#### TH121

##### **Are fine particles the most dangerous? An exposure and dosimetry approach**

F. Sánchez Soberón, Universitat Rovira i Virgili / Chemical Engineering; M. Mari, Rovira i Virgili University / Chemical Engineering; V. Kumar, Universitat Rovira i Virgili / Chemical engineering department; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering

Particulate matter (PM) is a complex mixture of extremely small particles and liquid droplets suspended in the atmosphere. Small particles in ambient air are originated from a wide range of sources (such as traffic, industry, energy production or domestic combustion). The inhalation of PM causes many adverse health effects on the population. In order to control their levels, PM outdoor concentrations, specially PM<sub>10</sub> and PM<sub>2.5</sub> fractions (those smaller than 10 and 2.5 µm of diameter respectively), are widely monitored. However, in developed countries population spend most of their time indoors. Data regarding indoor aerosol particles are not usually available, so "Indoor Aerosol Modelling" can be used as an alternative to estimate indoor levels. Apart from PM levels, health effects caused by PM depend on its physical and chemical properties. Size plays a key role on determining the part of the respiratory tract where the particles deposit and, therefore, their potential of being harmful. The objective of this study was to evaluate the exposure, indoor and outdoor, to different fractions of airborne particles and assess the dose retained in the different parts of the human respiratory tract. To do that, outdoor concentrations of three PM fractions (10, 2.5 and 1 µm) were measured in Montcada i Reixac (Barcelona, Spain), an area with many industrial activities (a cement plant among them). The outdoor concentrations were used to estimate indoor levels of PM fractions by means of Indoor Air Quality (IAQX) model (US EPA) taking into account the time activity patterns for different groups of population. In turn, Multiple Path Dosimetry (MPPD2.11) model was used to determine the internal exposure and the distribution of different PM fractions in the respiratory tract. The results showed that the pattern of exposure to particles changes significantly when considering different activities and indoor concentrations. Conclusions of this study may be a key factor for a better understanding of biological response to PM exposure and, hence, the human health risk assessment.

#### TH122

##### **Exposure assessment of airborne endotoxin, glyphosate residues, and particles in farms during summer spray season**

A. Adhikari, Georgia Southern University / Department of Environmental Health Sciences

Many low-molecular weight chemicals including some pesticides and herbicides are capable of inducing occupational asthma. Glyphosate [(N-phosphonomethyl) glycine] is one of the most commonly used broad spectrum nonselective herbicides in the world. Glyphosate application was associated with asthma and rhinitis in large-scale epidemiological studies of US farmers and a possible role of glyphosate in airway inflammation was previously shown in our laboratory study. Levels of airborne endotoxin and dust particles in farm environments are typically high as well. The cumulative exposures to endotoxin, glyphosate residues, and dust particles in farms could be associated with airway inflammation and asthma among farmers. In this field study, we have examined parallel exposure levels of airborne endotoxin, glyphosate residues, and particles of different sizes in several large corn farms of U.S.A. during summer glyphosate spray seasons. Samples were collected by conventional and non-conventional size-selective aerosol sampling/source testing methods (for aerosolizable contaminants from ground surface) before and during/after spraying. Extracts of aerosol samples were analyzed for endotoxin and glyphosate by *Limulus* amoebocyte lysate assay and glyphosate-specific ELISAs. Higher levels of endotoxin and glyphosate were observed in >1.8 µm particle size fractions and total inhalable aerosols compared to other particle size fractions. Endotoxin levels in air were found to be same during pesticide spray and in control samples. Reaerosolizable glyphosate residues and endotoxin on farm soil surfaces after spray were mostly below the detection limits. Glyphosate spraying in all farms increased particle concentrations for all sizes (0.3 - >20 µm), however, the increasing trends were more prominent for particles of >3 µm sizes.

##### **Environmental risk assessment for human exposed to airborne silica dust in ceramics manufacturing**

Y. Lin, B. Wu, Y. Cheng, Y. Shu-Han, National Taiwan University / Department of Bioenvironmental Systems Engineering; N. Hsieh, Department of

Bioenvironmental Systems Engineering; C. Liao, National Taiwan University / Department of Bioenvironmental Systems Engineering

Airborne pathogenic dust of silica (SiO<sub>2</sub>) is poised to be one of the greatest threats to human health effects, causing pulmonary fibrosis (silicosis), lung function deficits, pulmonary inflammation, and lung cancer. The purpose of this study was to assess human health risk exposed to airborne silica dust in Taiwan ceramics manufacturing. We conducted measurements to characterize the workplace-specific airborne silica dust in tile and commodity ceramic factories and used a physiologically based alveolar exposure model to estimate internal exposure dose. We constructed the dose-response models for describing the relationships between exposure dose and inflammatory responses, by which health risks among workers can be inferred. We found that silica contents were 0.22 – 33.04% with concentration ranges of 100 – 5336.86 and 0.46 – 1763.30 µg m<sup>-3</sup>, respectively, in tile and commodity ceramic factories. We showed that granulation workers in tile ceramic factory had the highest total silica lung burden (~1000 mg) with a cumulative silica lung burden of ~4 × 10<sup>4</sup> mg-yr. The threshold estimates that workers are exposed to are sufficient to have an effect on human health for inflammation and fibrosis are 407.31 ± 277.10 (mean ± sd) and 505.91 ± 231.69 mg, respectively. For granulation workers, a long-term of 30 – 45 yr exposure to airborne silica dust was likely to pose severe adverse health risks of inflammation and fibrosis. We suggest that proprietors should provide health examination to prevent the associated occupational disease attributable to long-term exposure of inhaled silica dust.

#### TH124

##### **Evaluation of the Exposome: Non-targeted screening analysis of environmental contaminants in human urine by liquid chromatography coupled to high resolution mass spectrometry**

A. Cortéjade; A. KISS, Institut des Sciences Analytiques / TRACES Team; C. Cren, Institut des Sciences Analytiques UMR TRACES Team; E. Vulliet, CNRS; A. Bulete, Institut des Sciences Analytiques UMR TRACES Team / Service Central d'Analyse

The impact of the environment on human health has been conclusively demonstrated. In recent decades, scientists have shown that many chronic diseases are related to our environment. In this context, a new term was born in 2005: the Exposome. It corresponds to all types of exposures humans are subjected throughout their lives via lifestyle, diet, and social environment, as well as the body responses to these exposures. The exposures the man is facing are numerous and all environmental contaminants present in everyday life are part of the Exposome. So the concept of the Exposome highlights the need to develop measurement methods to evaluate human exposures. Furthermore, the Exposome is an unstable concept that evolves over time. Therefore, it is necessary to rapidly establish sensitive routine measurement methods. In this context, a method was developed on crude urine and on a LC-ToF instrument to detect metabolites and degradation products of known or even unknown contaminants in contact to man in daily routine by a comprehensive approach. The developed analytical strategy consists in a broad screening of the urine based on the exact monoisotopic mass of the environmental contaminants, their metabolites and degradation products contained in urine. The urine appears to be the preferred biological matrix for studying the Exposome: it is easier to obtain (non-invasive, readily available) and includes a large number of endogenous and exogenous metabolites. This study focuses on the comparison of urine mapping from different cohorts with the aim of further studying the Exposome and upgrading the databases. The implementation of this tool to measure the Exposome associated with statistical studies, contribute greatly to the understanding of the causal relationships between diseases and environmental factors. Keywords: Exposome, LC-HRMS, urine, screening

#### TH125

##### **Improving the design of biomonitoring studies for persistent organic pollutants: Insights from population based pharmacokinetic modeling**

T. Bui, IVL Swedish Environmental Research Institute Ltd / Natural Resources Environmental Effects; A. Palm Cousins, IVL Swedish Environmental Research Institute Ltd; M. MacLeod, ITM - Stockholm University / Dept of Environmental Science and Analytical Chemistry ACES; I.T. Cousins, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; J. Mueller, Entox / National Research Centre for Environmental Toxicology Entox

Persistent organic pollutants (POPs) have been of great concern over the last few decades. Various biomonitoring programmes have been developed on a national or international scale to monitor the levels and trends of POPs in human populations. However, many challenges have to be faced when planning and conducting a biomonitoring study, for instance sampling (recruitment, matrix to sample, sampling frequency, area of sampling), storage and analysis (pooled or individual samples) and data evaluation. Since these studies can be very expensive, cost-efficient strategies are required. The aim of this work is to provide guidance on how to design a biomonitoring study to assess time trends of POPs in the general human population. Recommendations regarding cost-efficiency are offered and tools for evaluating the effectiveness of an action (e.g. restriction) to reduce exposure are presented. A key tool used in this study is the one-box, dynamic pharmacokinetic model developed by Ritter et al. in 2009. This work distinguishes between two important phases during a typical timeline of a POP: 1) Pre-action or increasing exposure phase and 2) Post-action or decreasing exposure phase. During

the pre-action phase, body burdens showed no differences between younger and older adults. Therefore, cross-sectional sampling of a population is not required. In the post-action phase, simulations show different results depending on the intrinsic elimination half-life of a chemical. Rapidly eliminated chemicals showed the same pattern as in the pre-action phase, but clear age-concentration relationships could be observed for chemicals with slow elimination rates, where older adults have substantially higher body levels than young adults. Since intrinsic elimination is mostly unknown, it is recommended to sample cross-sectional during this phase in order not to potentially underestimate body levels for older adults. During this phase, it is also possible to evaluate the effectiveness of an action by estimating turn-off ages (the age where concentrations reach a plateau and cease to increase) in cross-sectional data. Modelling results revealed a key turn-off age of 25 + number of years after peak exposure, below which more aggressive actions to reduce exposure will likely result in lowering the overall body burden of the population further. At turn-off ages equal or higher than that value, further actions will have no significant effect on the population.

## TH126

### Comparative exposure to DEHP from food contact materials: application of the product intake fraction

A.S. Ernstoff, Quantitative Sustainability Assessment; O. Jolliet, University of Michigan / Environmental Health Sciences School of Public Health; P. Fantke, Technical University of Denmark / Quantitative Sustainability Assessment Food contact materials (FCM), e.g. bottles and food handling gloves, can contain potentially endocrine disrupting chemicals, such as di-2-ethylhexyl phthalate (DEHP, CAS: 117-81-7). To investigate the contribution of FCM to dietary DEHP exposure we apply the product intake fraction (PiF: g intake/g in product) – a metric accounting for human intake of chemical mass per unit of mass embodied within a product. PiF of ingestion of DEHP is estimated from empirical data for PET water bottles on the order of 1E-7 through 1E-5 and for food handling gloves from 1E-6 for rice and 1E-3 for radishes. The uncertainty is related to unknown information (chemical content in FCM), circumstances of use (e.g. food item), and any analytical uncertainty. Using PiF, maximum allowable concentrations of DEHP within water bottles and gloves were calculated with respect to regulatory thresholds. A hypothetical average PiF for the FCM sector was calculated via production volume and oral exposure doses estimated from NHANES data. In both cases the indication was gloves may contribute more to DEHP exposure when used with certain food items than bottled water. DEHP content in gloves greater than 5% would cause exceedance of US EPA threshold when used with certain food items, e.g. radishes based on PiF calculated here. The PiF used in this context has applications for regulations related to FCM and exposure assessments on a per unit kilo basis.

## TH127

### Tissue dosimetry modeling of chemical mixtures containing Metals: a case study of Cd, Hg and Pb in humans

V. Kumar, Universitat Rovira i Virgili / Chemical engineering department; M. Nadal, University Rovira i Virgili / Laboratory of Toxicology and Environmental Health; J.L. Domingo, Universitat Rovira i Virgili / Laboratory of Toxicology and Environmental Health; S. Karakitsios, A. Gotti, D.A. Sarigiannis, Aristotle University of Thessaloniki / Chemical Engineering; M. Schuhmacher, Rovira i Virgili University / Chemical Engineering Most of the current practices in the health risk assessments of exposures to chemicals and the subsequent regulatory measures are based upon data from studies on the individual chemical. However humans are simultaneously exposed to multiple xenobiotic chemicals (such as pharmaceuticals, metals, pesticides, volatile and semi-volatile organic compounds, etc.) that potentially possess a number of similar or different toxic effects. If more than one chemical enters the body, a potential arises for interactions among chemicals, their metabolites, and the biological molecules/systems. Consequently, the authorities are challenged to consider that this “chemical cocktail” or “total chemical load” does not produce unforeseen health effects. Combined action and interactions between chemicals, at high doses have been known for many years in the field of pharmacology. However, these in-situ experiences are not directly useful for predicting toxic effects of mixtures of environmental chemicals because the exposure levels of the general human population are relatively low and interactions occurring at high doses may not be representative for low-dose exposures. In case of toxic metals which are transported and eliminated through many common cellular mechanisms by “molecular mimicry” because of their similarities to essential metals, therefore, there exist toxicokinetic and toxicodynamic interactions among toxic and essential metals. Metal absorption, elimination, and toxicokinetics should therefore be considered highly correlated for exposed individuals, with susceptibilities resulting in differential effects of multiple metals. In this study, we analyse the toxicokinetic and toxicodynamic of Cd, Hg and Pb using generalized whole body physiologically-based pharmacokinetic (PBPK) models for a case study in Spain. Physiological variability in the population is considered across the model by linking with biological databases that provide physiological values for a majority of the tissues groups. Interaction effects between the study heavy metals mixtures are incorporated. Model has been validated with data from previous studies (1998-2007) of human exposure to metals in autopsy tissues of individuals living near a waste incinerator.

## Effect Modelling of environmental systems - extrapolation and prediction of species response (P)

## TH128

### The use of dynamic population-level predictions in PERA: challenges and opportunities

C. Rendal, Unilever / Safety and Environmental Assurance Centre; O.R. Price, Unilever / Colworth Science Park; B. Goussen, University of York / Department of Environment; R. Ashauer, University of York / Environment Population-level models are increasingly recognised as potentially powerful tools in environmental risk assessment. However, the practical application of dynamic population predictions for decision making is not straight forward in everyday risk assessment of down-the-drain chemicals. Probabilistic environmental risk assessment (PERA) has been suggested as a way to make uncertainty more explicit and to account for spatial and temporal variability. The outcome of a PERA is typically a measure of expected risk with an associated uncertainty interval. We present a conceptual framework that explores how probabilistic approaches can be applied in population models to incorporate more ecological relevance into risk assessments while keeping both uncertainty and variability explicit and transparent. One of the key challenges is understanding the protection goals for ecological scenarios exposed to anthropogenic stressors. For instance, systems that are already impaired by high volume emissions of untreated wastewater may require modified protection goals (e.g. protection of microbial purification processes and recovery of food web structure and diversity). For higher organisms, the protection goals must be reflected by a defined set of endpoint metrics that can quantify changes in population-level dynamics. These metrics must be carefully selected based on both the specific scenario and protection goal, as different options will lead to very different interpretations of effect. Finally we discuss the importance of making the relation between the willingness to accept risk and the severity of the effect explicit to facilitate decision-making. We consider these discussions a necessary first step in bringing the full potential of population-level models into risk assessment of down-the-drain chemicals.

## TH129

### Interspecies QAAR for pharmaceuticals

A. Sangion, DiSTA; S. Cassani, P. Gramatica, University of Insubria / DiSTA Due to their extensive and progressive use in human and veterinary medicine, pharmaceuticals have been reported to be ubiquitously in surface and waste waters and are widely considered emerging environmental contaminants. Moreover, pharmaceuticals are specifically designed to be biologically active and their presence in the environment may be cause of serious concern for the wildlife. Even though a lot is known about pharmaceuticals' human toxicity, there is a lack of knowledge about their potential environmental hazard and ecotoxicology. In-silico approaches, like those based on quantitative structure–activity relationships (QSARs), are valuable tools able to maximize the information contained in existing experimental data; in particular, quantitative activity-activity relationships (QAARs) allows to find out the interspecies correlations and to predict missing information extrapolating from one species to another. In this study we present different interspecies toxicity models between *Daphnia magna* and *Pimephales promelas*, between *Daphnia magna* and *Oncorhynchus mykiss* and between the two species of fish *Pimephales promelas* and *Oncorhynchus mykiss*, for the prediction of acute toxicity of many pharmaceuticals chemicals. In addition to the pure correlation QAARs, we also propose models based on species response and a selected molecular descriptor by the all-subset procedure included in QSARINS software, starting from a matrix of hundreds calculated 0D-2D descriptors by PaDEL-Descriptor software. All models presented are stable, robust and validated ( $R^2 > 0.75$  and  $Q^2_{loo} > 0.70$ ) and can be used to extrapolate acute toxicity from and to different trophic levels. Particular attention was given to the structural applicability domain (AD) of the proposed models. We also analyzed the different correlations between the species, highlighting which ones were more correlated and which descriptors have more influence on them. Finally we applied the developed models to predict acute toxicity where data, for at least a species, were present and we compared the predictions derived from different models for the same chemical in order to propose consensus models to extrapolate information from crustacean to fish level.

## TH130

### Food web models as a tool for ecological scenario analysis

K.P. Viaene, Ghent University / GhEnToxLab; F. De Laender, Universit   de Namur ASBL / Laboratory of Environmental Ecosystem Ecology; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit One of the main challenges when evaluating the risk of a chemical for the environment is how to incorporate the large variation between and within ecological systems. A possible approach to deal with this diversity in biotic and abiotic conditions is to perform risk assessments for a selected set of possible scenarios. Standard scenarios cover a wide set of abiotic conditions e.g. spatial dimensions, hydrodynamics, physicochemical properties of chemicals and emission characteristics. Biological attributes also need to be accounted for e.g. the

degree of isolation or the presence of a predator will contribute to the vulnerability of populations and food webs. It is therefore important to assess the impact of both abiotic and biotic factors on the ecological effects of a chemical. Here, a spatially-explicit food web model was applied to assess the impact of three biotic attributes in ecological scenarios: degree of isolation, food web configuration and life cycle properties (e.g. generation time). The food web model was based on the Dynamic Energy Budget concept in its DEBkiss format. Each species in the food web was described by a DEBkiss individual based model. With this approach, the number of parameters per species was limited, allowing for easy manipulation of the life cycle properties. Different food web configurations were tested by manipulating the number of competing species and predators. The degree of isolation was changed by altering the spatial configuration of individual populations and the migration potential of a species. Using the food web model, we were able to quantify the impact of biotic variables on the outcome of a chemical stress event. We evaluated the relative contribution of each biotic attribute and assessed their importance for ecological risk assessments.

#### TH131

##### **Effect of metals in estuarine organisms: modelling toxicity in physiologically changing systems**

A. de Souza Machado, Leibniz Institute of Freshwater Ecology and Inland Fisheries / Ecophysiology and Aquaculture; W. Kloas, Leibniz Inst. of Freshwater Ecology & Inland Fish.; C. Zarfl, University of Osnabrueck / Center for Applied Geosciences In contrast to freshwater, where organisms are hypertonic regulators, saltwater environments allow a much broader diversity of physiological strategies. Marine creatures can hypo/hyper-regulate or even conform to ionic and osmotic pressures of surrounding waters. In estuaries, the frequent salinity changes make shifts in ion-osmoregulation strategy critical for survival. Modelling toxicity in estuarine species is related to changing physiology as a major challenge in metal ecotoxicology. Changes in membrane transporters and their composition and internal metal availability caused by salinity-driven metallothionein adaptations affect contaminant uptake and organism sensibility or sensitivity. Such enantiostasis processes mask the effects of metal causing toxicity. Also, most knowledge regarding metal toxicity to aquatic organisms has been established in freshwater, and suggested that the common mechanisms of toxicity are related to ion and osmotic disturbances driven by ion gradients between organism's plasma and environmental water. However, the lack of models accounting for the enantiostatic processes restricts our ability to explain and forecast toxicity in saline gradients. Thus, this study presents a mechanistic model to explain metal toxicity to aquatic organisms due to changing salinity. We propose a conceptual model able to incorporate published results of Cu and Cd effects on estuarine animals. The toxicity in this model is explained by variation on internal ion concentrations, assuming failure in ion-regulation as the main mechanism of action. In turn, internal ion content is represented by parameterization of water chemistry, metal exposure, and enantiostasis outcomes. The implication of this model is that water chemistry explains most of the metal toxicity in freshwater systems, where an ion-osmoregulation strategy is possible and small changes in water chemistry cause major modifications in metal speciation. In saltwater, however, the organisms' physiology is dominating the toxicity process, while enantiostasis is important at intermediate salinities. This mechanistic model is able to integrate conflicting published results where metal toxicity is claimed to be dependent on water chemistry or physiology. Ultimately, it also points out that more metal toxicity mechanisms are to be discovered, especially for exposures occurring at high salinities.

#### TH132

##### **A standardized approach to identify worst-case FOCUS surface water exposure profiles in aquatic pulsed exposure events**

O. Körner, ADAMA Deutschland GmbH / EU Registration; D. Nickisch, Environmental Fate Modeling The outcome of Tier 1 risk assessment (RA) for plant protection products (PPPs) frequently calls for the use of higher tier approaches to provide an acceptable risk to aquatic organisms. In this context, laboratory pulsed exposure experiments can be used to test for the effects of varying exposure concentrations as it is often the situation in the field. However, selecting the relevant exposure scenarios is highly challenging and often based on subjective expert judgements. TK/TD models are a useful tool that accounts for time variable exposure concentrations and predicts toxicity on organisms. They allow extrapolating toxic effects beyond test conditions while considering real time carry-over toxicity. Hence, TK/TD models provide one means to determine worst-case exposure scenarios in a more scientifically sound way. Here, we present a step-wise approach whereby we use the TK/TD model GUTS to determine the exposure scenario with the strongest impact on organisms. We generate exposure profiles from the different representative EU surface water scenarios defined in the FOCUS-SW models. These models consider various entry pathways of PPPs into the aquatic environment, mainly spray-drift, run-off and drainage. Contrary to the first two pathways for which mitigation measures are available, entry via drainage cannot be reduced and represents the most frequent case for conducting higher tier RA. Besides, entry via drainage can vary considerably in comparison to drift or run-off, leading to more complex exposure profiles. Thus, we select our test substance and application pattern in a way that drainage is the main entry pathway to aquatic

systems. The GUTS model is calibrated using survival data from laboratory tests. Using the generated predicted exposure patterns from FOCUS-SW models as input, we run GUTS simulations over the entire time period defined in the FOCUS models and predict survival. The comparison of the predicted organisms' responses in the different simulated exposure scenarios allows the identification of the worst-case exposure scenario and subsequently, the selection of the relevant exposure profile window to be tested in the pulsed exposure test. Results of this study would significantly improve our understanding of the link between exposure and effects and highlight the importance of TK/TD models in higher tier RA schemes.

#### TH133

##### **EE2 impacts on zebrafish population dynamics extrapolated from organism-level endpoints using a DEB-IBM model**

R. Beaudouin, INERIS / Models for Ecotoxicology and Toxicology METO; J. Devillers, CTIS; F. Brion, INERIS / Ecotoxicology Unit; A.R. Pery, INERIS / TOXICOLOGY AND ECOTOXICOLOGY MODELING UNIT Data used to estimate the likelihood of adverse ecological effects typically include responses of survival, growth, or reproduction of individuals measured after a specific exposure duration under constant laboratory conditions and in absence of ecological stress (e.g. predation and competition). These organism-level endpoints are far from the ecological features that the process aims to protect. Indeed, ecological risk assessment should protect the long-term persistence of populations of species in space and time under naturally varying field conditions and in the presence of other stressors (e.g. food limitation). In this context, population models can play an important role in bridging the gap between what is measured (organism-level endpoints) and what needs to be protected (population-level endpoints). Zebrafish (*Danio rerio*) is an attractive vertebrate model for investigating chemical ecotoxicity and to address the issues posed by Endocrine Disrupting Chemicals. Consequently, an individual-based model (IBM) of the population dynamics for zebrafish was developed in order to extrapolate from toxicity data measured on organism to biological levels relevant to support and enhance ecological risk assessment. The zebrafish population dynamics model was developed by coupling a DEB model with an IBM, and by integrating the main ecological factors (photoperiod, temperature, and food dynamics). The predictive capability of model was assessed with the 17 $\alpha$ -ethinylestradiol (EE2). Indeed, abundant data was published on the EE2 impacts on organism-level endpoints and can be used to define the dose-response relationships integrated in our population model. In addition, at least one experiment was conducted at the population level with this compound [1] and could be used to test the predictions of our model. Two different cases were tested: (i) the exposure scenario conducted by Kidd et al. [1] and (ii) a discontinue exposure at different concentrations environmentally relevant. The exposure periods of the second scenario were defined using the sensitivity analysis of the model to define the worst case. Our model provided predictions comparable to the observations reported by Kidd et al. [1] notwithstanding the ecophysiology differences between the two species used. [1] Kidd KA, Blanchfield PJ, Mills KH, Palace VP, Evans RE, Lazorchak JM, Flick RW, 2007. Collapse of a fish population after exposure to a synthetic estrogen. Proc Nat Acad Sci USA 104:8897-8901.

#### TH134

##### **A generic approach to modelling mayfly population dynamics in the field**

L.M. Wagenführ; T. Strauss, Research Institute gaiac / Research Institute Gaiac; S. Classen, gaiac Institute for Environmental Research RWTH Aachen; T.G. Preuss, Bayer CropScience / Environmental Modelling; A. Schaeffer, RWTH Aachen University / Institute for Environmental Research; A. Gergs, RWTH Aachen University / Department of Environmental Social and Spatial Change In scientific and regulatory communities, individual-based models are gaining resonance as a tool to bring more ecological realism and more informed effect predictions into the environmental risk assessment of chemicals. In particular, standard model designs are thought to facilitate the acceptance and usage of mechanistic effect models. Therefore, we tested a generic individual-based model for its applicability to *Cloeon dipterum* an ephemeropteran species common in Europe. Ephemeroptera in general represent a considerably part of secondary production. Hence, the Ephemeroptera larvae have specific biotope requirements they are frequently used for the characterisation of water bodies. The larvae are also known to be sensitive to pollution, but due to their life cycle, chronic toxicity tests with mayfly larvae are complex and costly. In the model, the lifecycle of each *C. dipterum* individual is described based on equations provided by the dynamic energy budget (DEB) theory. DEB models describe key life history processes such as growth, maturation and reproduction as functions of the energy gained from food assimilation. Similar to real life, modelled population dynamics emerge from individual life histories and interactions of individuals with their environment. Model parameterisation was largely based on literature data; however, a few data gaps have been filled by additional experiments. The literature review also revealed that the standard DEB model had to be adapted to match the ephemeropteran life history strategy. For model testing, the simulation outcomes were compared to data derived from mesocosm studies. In model applications, it was investigated to what extent environmental factors such as temperature, resource availability and predation may trigger seasonal emergence patterns of mayflies.

#### TH135

### **Spatially-explicit population modelling as a refinement tool for soil invertebrates risk assessment**

M. Meli, J. Ludwigs, Rifcon GmbH

Ecological effect models can be an important instrument to add ecological relevance to terrestrial risk assessments. Current refinement options include *ex situ* bioassays, Terrestrial Ecosystem Models and field surveys, share some limitations, such as the difficulty to link observed effects to a specific toxic component in the soil and to find a proper reference site or soil. Ecological effect models mechanistically link effects at individual level to impacts at the population level, and allow comparison of different contaminated scenarios to a control situation. Unlike in field survey, ecological models allow for an easier interpretation of the results, distinguishing between effects of the different factors implemented, and are therefore a valuable refinement tool for soil risk assessments. We developed a spatially explicit individual-based model of the collembolan *Folsomia candida*, designed specifically for conducting population-level risk assessments of pesticides. The purpose of the model is to realistically reproduce population dynamics of *F. candida* with special focus on the dynamic spatial distribution of individuals and on density dependent population regulation. Model rules and parameters are based on data from the literature. For toxicity, data from standard laboratory tests (survival and reproduction) are used; for exposure soil load, application date and DT50 are required. The model has been parameterized and evaluated using Pattern Oriented Modelling: here models are required to simultaneously reproduce a diverse set of patterns. Landscapes used in the simulations represent part of an agricultural field. Environmental variability is represented by the inhomogeneous distribution of food resources in the landscape. Temperature is implicitly taken into account because it affects the values of several life-cycle parameters. Temperature profiles are derived from the meteorological data used in the FOCUS GW models. Soil moisture is also implicitly represented in the model and it affects the availability of food resource. For model output population density over time is recorded. Therefore, it is possible to assess reductions of population density caused by agrochemicals and potential for recovery. Model outputs are thus directly linkable to specific protection goals established for soil invertebrates. Results based on a hypothetical substance, and insights gained from using the model for risk assessment submissions will be presented.

### **TH136**

#### **MOSAIC: a web-interface with modelling and statistical tools for ecotoxicology**

S. Charles, University Lyon 1 / Laboratory of Biometry and Evolutionary Biology; P. Veber, Université Claude Bernard Lyon 1 / Laboratoire de Biométrie et Biologie Evolutive; M. Delignette-Muller, VetAgro Sup / Laboratory of Biometry and Evolutionary Biology

In ecotoxicology, bioassays are classically conducted according to standard protocols to measure acute or chronic effects of potentially toxic substances on reproduction, growth and/or survival of living animals. MOSAIC, standing for “*Modeling and Statistical tools for ecotoxicology*”, is a new user-friendly web interface dedicated to the mathematical and statistical modelling of such bioassay data. Its simple use makes MOSAIC a turnkey decision-making tool for ecotoxicologists and regulators. Without wasting time on extensive mathematical and statistical technicalities, users are given advanced and innovative methods for a valuable quantitative environmental risk assessment. MOSAIC is available at <http://pbil.univ-lyon1.fr/software/mosaic/>. Today, MOSAIC offers two operational modules : (i) MOSAIC\_SSD, a tool dedicated to the species sensitivity distribution (SSD) approach aiming at defining safe levels for toxic compounds in an ecosystem through the calculation of the so-called hazardous concentration for *p*% of the species (*HCp*), even when the toxicity values are censored [1, 2]; (ii) MOSAIC\_repro, which provides users with a (complete) statistical analysis of bioassay reproduction data simultaneously accounting for mortality all along the bioassay. For that purpose, concentration-effect models are fitted within a Bayesian framework. This poster will be organized as a user guide of MOSAIC, with a succession of screenshots illustrating how to analyse data in two simple and user-friendly steps. Details will be given on the different graphics provided by MOSAIC, but also on the way results maybe saved as they are or personalized within the R software.

### **TH137**

#### **Metals risk assessment in aquatic systems using integrated modelling approach to unveil responses at different biologic organizational levels, from gene to population.**

R. Ben-Hamadou, Qatar University / Department of Biological and Environmental Sciences; D. Piló, IPMA Portuguese Institute for the Sea and Atmosphere; P. Pereira, Department of Biology and CESAM; A.M. Marques, CESAM e Departamento de Biologia; R. Rodrigues, CESAM & University of Aveiro; A. Carriço, University of Aveiro / Department of Biology and CESAM; F. Pereira, IPMA Portuguese Institute for the Sea and Atmosphere; A. Leitão, Qatar University / Environmental Studies Centre ESC; M. Gaspar, IPMA; C. Vale, IPMA Instituto Portugues do Mar e da Atmosfera; M. Pacheco, University of Aveiro / Dept of Biology; S. Mendo, University of Aveiro / Department of Biology CESAM; S. Carvalho, King Abdullah University of Science and Technology - KAUST / Red Sea Research Center

Metal contamination in estuarine environments is a major concern since organisms may accumulate metals above a toxic threshold limit. However, relationships between metal contamination and ecological effects are often unclearly defined, considering the potential occurrence of tolerance mechanisms in aquatic organisms that can be activated with exposure to metals. Additionally, stress may trigger responses at different organizational levels, theoretically, from gene to population. The complexity of those responses may be encompassed by coupling multidisciplinary field studies and experiments with advanced data mining methodologies. The present study aimed to identify the effects of metal contamination on the macrobenthic biota at different biological levels as well as the linkage between these responses using machine learning algorithm. Two bioindicator species (the Manila clam: *Ruditapes philippinarum* and the common cockle: *Cerastoderma edule*) occurring in the metal contaminated Tagus estuary (Portugal) were considered. Multi-class classification modelling tool was applied using various class of the input data (hydrological features, sediment grain-size, metal levels in both species tissues and sediment) to predict the level of response (or model outputs) in the considered two populations (gene expression of metallothioneins, chromosome abnormalities, oxidative stress, size-frequency structure and biomass). Results showed a complex stress response of both populations to the four considered levels of metal contamination. The type of stress (metal contamination) and the level of the stress (contamination level) were determinant to classify changes in the biological responses suggesting a differential population stress response as a function of the major metal contaminant and the level of contamination. Changes at the molecular level (gene expression and oxidative stress) were associated to medium-high levels of redox-active metals contamination (such as chromium). In contrast changes at the population level were associated mainly to only high levels of metal contamination suggesting a buffering of molecular stress responses for lower levels of contamination either for redox (active or inactive) metals. Our results suggest that differential biological responses may occur in a population considering the typology and the level of metal contamination and that metal risk assessment should integrate these novel findings when selecting the monitoring endpoint.

### **TH138**

#### **An Individual Based Model of the Eurasian minnow, a representative vulnerable fish for pesticide risk assessment**

I. Ibrahim; C.R. Hazlerigg, Imperial College / Division of Biology; T.G. Preuss, Bayer CropScience / Environmental Modelling; V. Grimm, Helmholtz centre for environmental research - UFZ / Department of Ecological Modeling; U. Hommen, Fraunhofer IME

We present an individual-based model for the Eurasian minnow *Phoxinus phoxinus*. The proximate purpose of this model is to reproduce the field population dynamics of the Eurasian minnow in edge-of-field streams in the European temperate region with the ultimate aim to allow population-level ecological risk assessment (ERA) of pesticides in edge-of-field water bodies especially when sub-lethal effects are possible. The model species was carefully selected for this purpose to be a vulnerable representative of the field situation in terms of potential exposure to pesticides and population resilience to possible adverse effects of pesticides on reproduction. The model handles the minnow population dynamics by accounting for individual variability and the effect of population density on individual growth and of habitat preference and reproductive behavior on individual survival. Model design and parameterization are based on field data and demographic patterns which had been reported since 1940 and till this day, for minnow populations in general while focusing on populations in temperate regions. Before the model can be used to extrapolate from results of eco-toxicological tests to field population it was first important to test the IBM on patterns observed for unaffected populations in the field so that pesticide case studies later can reflect potential effects with a certain degree of confidence. The poster presents the model description and testing following the TRACE protocol. Additionally, the model applicability to ERA is demonstrated in an example for chronic effect assessment.

### **TH139**

#### **Spectral Granger causation in the dynamic interaction of biological and environmental systems**

J. Val, San Jorge University; M. Pino, San Jorge University / Facultad ciencias de la salud; D. Chinarro, San Jorge University

Global change effects, coupled with anthropogenic pressures, are transforming freshwater ecosystems, mainly through changes in basin flow dynamics. Ebro river basin belongs to a Mediterranean area characterized by a strong impact of climate change and also suffering a high hydrological control nowadays. For the causality analysis between both; time series of river metabolism and environmental events (human and climate), an emerging methodology has been performed among nonparametric spectral methods to include the estimation of Granger causality spectra for reveal directional influences or dynamical interaction of biological and environmental systems. Granger causality test has been applied into frequency domain of pair of time series to be compared using wavelet method. In recent decades the wavelet spectral analysis has been considered as a powerful method for the analysis of variability in time series. Nevertheless, until now, wavelet methods have scarcely been applied to the study of the river metabolism. Moreover, Granger test. After transforming time series into scale components to accommodate for their multi-horizon dynamics, linear and non-linear Granger causality tests are

performed. Essentially the test inquires whether, knowing the autocorrelation of one isolated variable, the error yielded in the forecast verification can be improved by taking in account the case of cross correlation with another variable. The work presents the suitability of wavelet methods for the interpretation of river metabolism. We have obtained the Granger tests in the spectral analysis of metabolism several time series (from up to 16 years long) from several Ebro river sub-basins. Different variability patterns have been observed in each case. These patterns have been associated with both climatic and anthropogenic changes. Our results also show that wavelet methods could be a useful tool for territorial organizations to obtain integrating environmental, economic and social aspects to make decisions in order to manage the basins.

#### TH140

##### Species Sensitivity Distributions for Non-Target Plant Studies

J.W. Green, DuPont / Applied Statistics Group

Species Sensitivity Distributions (SSDs) are increasingly requested by regulatory authorities, especially in the EU, as part of product registration submissions. There is some inconsistency among country regulators as to requirements and acceptable methods of fitting and interpreting SSDs, specifically estimating the concentration hazardous to no more than 5% of exposed species (HC5). A comparison will be made of the median HC5 and lower bound HC5 calculations. Specifically, the variability of the lower bound HC5 will be shown to greatly exceed that of the median HC5 estimate. It has become common in some EU registrations to reject species data for SSD purposes if the data do not conform to the log-normal distribution. There is no scientific basis for this requirement and it will be shown that the log-normal is not always appropriate and the consequence of mis-specifying the distribution can be a seriously misleading HC5 value. The EUFRAM work of several years ago recommended capturing uncertainty as well as variability, but some software packages ignore this and report unrealistically short confidence intervals. Datasets used for SSDs often contain censored values (e.g., EC50>100 ppm). Some EU regulatory authorities do not accept censored values. There is no scientific basis for such action and there have long been known mathematically correct ways to include censored values in fitting a distribution. That approach will be described and has been implemented in proprietary software, but only recently has a software package been widely available that implements this approach. That package, MOSAIC, and several other software packages for fitting a SSD and estimating HC5, such as ETX, BurrI/OZ, SAS, and SSD Master will be discussed and compared. Finally, some attention will be given to the number of non-target plant species needed for SSD fitting. While the focus of this presentation is on non-target plant studies, the issues presented apply to all SSD work.

#### TH141

##### Theoretically exploring direct and indirect chemical effects across ecological and exposure scenarios using mechanistic fate and effects modelling

F. De Laender, Université de Namur ASBL / Laboratory of Environment and Ecosystem Ecology; M. Morselli, University of Insubria / Department of Science and High Technology; h. bavoco, Environmental Risk Assessment Team; P. van den Brink, Alterra Wageningen UR / Aquatic Ecology and Water Quality Management Group b Alterra; A. Di Guardo, University of Insubria / Department of Science and High Technology

Predicting ecosystem response to chemicals is a complex problem in ecotoxicology and a challenge for risk assessors. The variables potentially influencing chemical fate and exposure define the exposure scenario while the variables determining effects at the ecosystem level define the ecological scenario. In absence of any empirical data, the objective of this paper is to present simulations by a fugacity-based fate model and a differential equation-based ecosystem model to theoretically explore how direct and indirect effects on invertebrate shallow pond communities vary with changing ecological and exposure scenarios. These simulations suggest that direct and indirect effects are larger in mesotrophic systems than in oligotrophic systems. In both trophic states, interaction strength (quantified using grazing rates) was suggested a more important driver for the size and recovery from direct and indirect effects than immigration rate. In general, weak interactions led to smaller direct and indirect effects. For chemicals targeting mesozooplankton only, indirect effects were common in (simple) food-chains but rare in (complex) food-webs. For chemicals directly affecting microzooplankton, the dominant zooplankton group in the modelled community, indirect effects occurred both in food-chains and food-webs. We conclude that the choice of the ecological and exposure scenarios in ecotoxicological modelling efforts needs to be justified because of its influence on the prevalence and magnitude of the predicted effects. Overall, more work needs to be done to empirically test the theoretical expectations formulated here.

##### Overview of NOAA Deepwater Horizon Natural Resource Damage Assessment toxicity testing program

J.M. Morris, Stratus Consulting; J. Lipton, Stratus Consulting, Inc.; C. Lay, Stratus Consulting; M. Krasnec, Stratus Consulting Inc.; H. Forth, Stratus Consulting; R. Takeshita; D. Cacula, Stratus Consulting Inc.; M.L. Gielazyn, NOAA / c/o USEPA, Region IV; R.W. Ricker, NOAA / Office of Response and Restoration  
In support of the *Deepwater Horizon* (DWH) Natural Resource Damage Assessment, we have conducted over 500 bioassays and related chemical

characterizations to determine the toxicity of DWH oil to native species in the Gulf of Mexico. The study matrix for this effort included over 25 species of fish and invertebrates; life stages ranging from gametes to adults; a suite of lethal and sublethal endpoints; four different DWH oils and dispersant; and exposure routes, including water accommodated fractions, surface slicks, and sediments. These studies were conducted by over a dozen collaborating university, government, and private laboratories. Analyses of these data are ongoing but we will discuss effects levels for a range of species, exposure chemistry, testing methods, and our meta-analysis of this dataset.

#### TH143

##### Toxicity of organic compounds toward *Saccharomyces cerevisiae* - An In Vitro Bioassay to Assess the Mutagenic Potency of Electrophiles

S. Schweiger, Helmholtz Centre for Environmental Research GmbH - UFZ / Ecological chemistry; G. Schuurmann, Helmholtz centre for environmental research - UFZ / Department of Ecological Chemistry

The European regulation REACH (Registration, Evaluation, Authorisation and Restriction of Chemicals) concerns the production and use of chemicals and their potential influence on human health and the environment. A major aim for REACH is the reduction of animal testing. In order to assess risk potentials of chemicals, the concept of integrated test strategies was developed, which combines data from alternative test methods, like in vitro, in chemico and in silico studies. In the aquatic ecotoxicology, the narcosis model describes that every chemical has a toxicity corresponding to the hydrophobicity. Substances with a lower EC<sub>50</sub> as compared to the corresponding baseline narcosis also have a higher toxicity, which can be specific or reactive toxic. The latter of which can be quantified by the toxicity enhancement T<sub>e</sub>. Reactive toxic chemicals can interact with biomolecules in cells where they build mostly irreversible covalent bondings, leading to enhanced toxicity, mutagenicity or skin sensitization. In this study a differential growth-inhibition bioassay with two yeast strains was used to evaluate the toxic potential of different organic substances. A strain without the gene *Rad54*, besides the wildtype of *Saccharomyces cerevisiae*, was used to determine the genotoxicity of substances. Rad54 is involved in the recombinational repair of double-strand breaks in DNA, that is why it can not repair DNA-doublestrand breaks and thus it is more sensitive to DNA-reactive substances. In our study the concentration of a substance which causes 50% reduction of growth of the yeast cells was determined (effective concentration at 50%, EC<sub>50</sub>). The ratio of the EC<sub>50</sub> of both strains can show that the test substance is genotoxic or rather destroys DNA-double strands (TR-value, toxic ratio). In order to determine the narcosis level of *S. cerevisiae* a narcosis baseline for both strains for substances from a log K<sub>ow</sub> of -1.36 to 5.13 were analysed. Two different substance classes, acrylates and sulfonates, were evaluated in the yeast-bioassay to test the reliability of the assay for reactive and genotoxic substances. All EC<sub>50</sub>-values were corrected for sorption and evaporation to quantify the freely dissolved fraction in solution. *Acknowledgement* - The authors thank the SAB (Sächsische Aufbaubank) for financial support (Contract-No: 100119621).

#### TH144

##### Dynamic modeling of physiological processes related to energy management in *Gammarus fossarum*

C. Lopes, Université Lyon 1, UMR CNRS 5558 / Laboratory of Biometry and Evolutionary Biology; F. Mounier, University of Lyon 1 / Laboratory of Biometry and Evolutionary Biology; S. Charles, University Lyon 1 / Laboratory of Biometry and Evolutionary Biology; a. chaumot, O. Geffard, Irstea / UR MALY Laboratoire Ecotoxicologie

Approaches for the assessment of environmental impacts of contamination rely on toxic effects observed mainly at the individual level. These effects are then extrapolated to higher levels of biological organization (population, community and ecosystem) that constitute the protection goals of environmental regulations (REACH, WFD). Individual performance is governed by the allocation of energy to the physiological processes. DEB theory (Dynamic Energy Budget) formalizes the allocation of energy to key physiological functions (growth, maintenance and reproduction). However, until now, these models assume a permanent energy allocation to the reproduction during the lifespan of an organism, while it is generally a discrete process driven by physiological constraints. This is particularly true for crustaceans for which reproduction is synchronized with molt, such as *Gammarus fossarum*, a keystone species playing an important role in the functioning of European freshwater ecosystems. The aims of our presentation are (1) to present a mechanistic DEB model describing the allocation of energy during a reproductive cycle of *G. fossarum* females exposed to different temperatures and (2) to illustrate how it can be used under stress conditions. According to the knowledge on *G. fossarum* reproductive cycle, we schematized the biomass fluxes occurring during a reproductive cycle and formalized them by six differential equations. Considering different temperatures and different sizes of females allowed to consider different feeding rate values for the calibration of energetic processes implied during a reproductive cycle. Parameters were then estimated by Bayesian inference: we obtained precise estimations for the parameters. In particular, we estimated that females allocate 12% [0.11-0.14] of the assimilated energy to reproduction and predicted that 83% of the observations were within the predictive credible intervals. The model was then validated on other data. Finally, we fixed the scheme of energy allocation and compared the model predictions with lower food inputs to what is observed when females are under such food limited

conditions. We showed that the more the food was restricted, the more the model underestimated reproduction, meaning that energy allocation was modified to privilege reproduction. Our study shows how a DEB formalism may describe the energy allocation processes of a crustacean for which reproduction occurs in a discrete way during successive molts.

#### TH145

##### **Reactivity of Aldehydes toward Amino Model Nucleophiles - A Chemoassay Approach to Identify Potential Skin Sensitizers**

A. Böhme, UFZ - Helmholtz Centre for Environmental Research / Ecological chemistry; C. Slawik, Helmholtz centre for environmental research - UFZ / Ecological chemistry; G. Schuurmann, Helmholtz centre for environmental research - UFZ / Department of Ecological Chemistry  
A key step in triggering allergic contact dermatitis is the sensitization of skin through dermal contact with allergens as industrial chemicals and cosmetic ingredients. Currently, skin sensitization potency is assessed by the murine local lymph node assay (LLNA), an animal test that is still the recommended method in REACH. The molecular initiating event of the adverse outcome pathway leading to skin sensitization is the covalent binding of electrophiles to nucleophilic target sites of dermal proteins and peptides. In this context, aldehydes are prominent candidates that can react with the  $\epsilon$ -amino group of lysine or the N-term. Employing model nucleophiles as surrogates for endogenous nucleophilic groups, kinetic chemoassays provide access to reactivity information in terms of second-order rate constants.<sup>1,3</sup> In this communication, a kinetic amino chemoassay is employed for assessing the electrophilic reactivity of selected aldehydes and Michael-type aldehydes toward the  $\epsilon$ -amino group of lysine and the N-term through the second-order rate constant  $k_{\text{NH}_2}$ . The results are compared with literature data for the compounds' LLNA potency in order to discriminate between non-sensitizing and potentially sensitizing candidates. 1) Böhme A, Thaens D, Paschke A, Schüürmann G 2009. ##### **Using the DEBKiss IBM framework to predict chemical effects on two interacting zooplankton species**

K.P. Viane, Ghent University / GhEnToxLab; A. Focks, Alterra Wageningen University and Research Centre / Ecotoxicology Environmental Risk Assessment Team; h. haveco, Environmental Risk Assessment Team; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; P.J. van den Brink, Alterra and Wageningen University; F. De Laender, Université de Namur ASBL / Laboratory of Environmental Ecosystem Ecology  
One of the objectives of the ecological risk assessment of chemicals (ERA) is the protection of higher levels of biological organization i.e. populations and ecosystems. Alternative approaches to the use of individual-level endpoints have been proposed to improve ERA e.g. the use of ecological models. A potentially important factor to consider in ERA are interactions between species because these can alter the outcome of chemical exposure. Individual based models (IBMs) seem particularly suited for use in ERA. Dynamic energy budget theory (DEB) was proposed as an underlying theory. Using the parsimony principle, the DEBKiss framework allows more transparency, reduces the amount of data required and increases the user-friendliness. In this study, we applied DEBKiss IBMs to two zooplankton species (*Daphnia magna* and *Brachionus calyciflorus*) using only existing literature data and without extensive calibration. As a first step, growth and reproduction of both species under different feeding conditions were predicted. Next, population simulations were compared with the results of a population experiment where both isolated and interacting *D. magna* and *B. calyciflorus* populations were exposed to pyrene. Both growth and reproduction were accurately predicted at low and high feeding conditions. However, reproduction and growth were overpredicted at intermediate feeding conditions. For *D. magna*, patterns of population dynamics compared well to those observed in the experiments: the population quickly grew to a maximum density after which the population declined. The negative effect of pyrene stress on *D. magna* population dynamics was also predicted accurately. For *B. calyciflorus*, predicted population dynamics compared well to the observations except at the end of the experiment, where population decline was observed but not predicted. This population decline of *B. calyciflorus* was possibly caused by depleted resources, which are not accounted for in DEBKiss. *B. calyciflorus* was not affected at the tested pyrene concentrations. DEBKiss IBMs were also successfully applied to *D. magna* and *B. calyciflorus* populations competing for phytoplankton. *B. calyciflorus* was outcompeted by *D. magna* after 14 days, similar to the population experiment. Using DEBKiss IBMs and available literature data, we have been able to successfully predict individual endpoints as well as population dynamics for both isolated and interacting *D. magna* and *B. calyciflorus* populations.

#### TH147

##### **Population modelling of threatened and endangered species: a review of available models to assess the risks of pesticides.**

J. Vavra, UNL-Lincoln / School of Biological Sciences; N. Galic, School of Biological Sciences / School of Biological Sciences; A. Schmolke, University of Nebraska Lincoln / School of Biological Sciences; R.A. Pastorok, Integral Consulting, Inc.; P. Thorbek, Syngenta / Environmental Safety; V.E. Forbes, University of Nebraska Lincoln / School of Biological Sciences  
In April 2014, CropLife America sponsored a Science Forum to gain a better understanding of the current status of population modelling and its role in assessing ecological risks of pesticides to threatened and endangered (T&E) species in the United States (US). Forum participants recommended that a comprehensive review of available population models be conducted to identify the most promising candidate models. We conducted a review of available population models, with consideration given to the availability of different classes of population models, the availability of parameters for model input, and the practicality of implementing the models for large-scale risk assessments (RA). Regulatory bodies in the US have struggled to reach a consensus on approaches to assessing the risks to T&E species, therefore our objective is to recommend candidate population models that can assist with implementation of population modelling in future ecological and endangered species risk assessments for pesticides. Given the European Union's continued forward progress in the use of population models for risk assessment; we feel this review will be useful to inform pesticide risk assessment in the EU as well as the US. This presentation provides the conclusions and recommendations of our literature review.

#### TH148

##### **Developing a Knowledgebase for the Prediction of Environmental Toxicity**

F. Ntie-Kang, University of Buea / Chemical and Bioactivity Information Centre; P. Judson, Judson foundation

There is widespread concern about the toxicological effects of man-made chemicals in the environment, including those of pharmaceutical products and their metabolites. There are databases of, and computer models to predict, aquatic narcosis and, in some cases, excess aquatic toxicity such as ECOSAR [1] but there remains a need for better sharing of human knowledge about the full range of environmental and human toxicological hazards. Computer programs such as Derek [2] are used to share human knowledge about mammalian toxicity and a proof of concept application using the same technology to share knowledge about toxicity to *Tetrahymena pyriformis* and human skin sensitisation has been described [3]. [1] Reuschenbach P., Silvani M., Dammann M., Warnecke D. 2008. ECOSAR model performance with a large test set of industrial chemicals. *Chemosphere* 71(10):1986-1995. #### TH149

##### **Toxicokinetic Toxicodynamic (TKTD) modelling of metal toxicity in freshwater organisms: whole-body sodium loss predicts acute Ag mortality across aquatic species**

K. Veltman, University of Michigan / Department of Environmental Health Sciences; J.A. Hendriks, Radboud University Nijmegen / Department of Environmental Sciences; M. Huijbregts, Department of Environmental Science; C. Wannaz, The University of Michigan, Ann Arbor / SPEHS; O. Jolliet, University of Michigan / Environmental Health Sciences School of Public Health  
Toxicokinetic Toxicodynamic (TKTD) models are considered essential tools to further advance acute toxicity prediction of metals for a range of species and exposure conditions, but they are currently underutilized. We present a mechanistic TKTD model for acute toxicity prediction of silver (Ag) in freshwater organisms. In this new approach, we explicitly link relevant TKTD processes to species (physiological) characteristics, which facilitates model application to other untested freshwater organisms. The toxicokinetic model quantifies the labile Ag concentration in the target organ (i.e. gill) as a function of the species-specific water ventilation/filtration rate and the metal-specific absorption efficiency. The toxicodynamic model quantifies the reduction in whole-body sodium concentration over time as a function of the target site inhibition over time, the target site density and the species-specific sodium turnover rate. Freshwater species are assumed to die instantly when they have lost a critical amount of their initial whole-body sodium concentration. Results show that mortality is significantly related to sodium loss ( $r^2 = 0.86$ ) for various aquatic organisms and exposure durations. Evaluation of the model with an independent acute toxicity data set for 5 organisms, including *Daphnia magna*, rainbow trout and juvenile crayfish, shows that the model accurately predicts time-specific lethal effect concentrations for these different freshwater organisms. In addition, the model is able to capture the observed size-specific variation of nearly two orders of magnitude in empirical  $LC_{50}$ s. We are currently performing a more extensive evaluation of the model and are testing its

capability to predict acute toxicity for a wider range of species ( $n = 12$  species,  $n = 30$  time- and species-specific  $LC_{50}$ s,  $n > 200$  total data) and its applicability to different exposure conditions (particularly different water chemistries and exposure durations).

#### TH150

##### **Modelling tissue-specific accumulation of metals in parasite-fish systems**

Y.T. Le, Radboud University Nijmegen / Environmental Science; M. Nachev, D. Grabner, University of DuisburgEssen / Aquatic Ecology; J.A. Hendriks, Radboud University Nijmegen / Department of Environmental Sciences; B. Sures, University of DuisburgEssen / Aquatic Ecology

In the environment, fish are affected by exposure to metals and infection with parasites. Moreover, each of these two factors may affect the response of fish to the other. Metal exposure may reduce the resistance of fish to parasites while parasites may have effects on metal accumulation and metallothionein induction in the fish host. A number of parasites have been reported to have remarkably high capacity of accumulating metals. Therefore, inclusion of parasites might provide more reliable assessment and more accurate interpretation of biomonitoring data. Currently, the partitioning of metals between parasites and their fish host is usually expressed by an empirical ratio of the metal concentration in parasites to that in the host. This factor does not provide a mechanistic understanding of underlying processes determining metal accumulation in parasite-fish systems. Effects of parasites on metal accumulation in the fish host cannot be explained by the uptake by the parasites only. Parasites might influence metal uptake and elimination in the fish host. In addition, parasitism might lead to changes in the subcellular partitioning in cytosolic and particulate fractions, therefore affecting the internal distribution of metals between fish organs. We developed a multiple-compartment model for predicting tissue-specific accumulation of  $^{210}\text{Pb}$  in chub *Squalius cephalus* uninfected and infected with the acanthocephalan *Pomphorhynchus laevis*. The model covers in seven compartments, namely blood, storage, gills, kidney, liver, intestine, and gallbladder. External and internal exchange in the model was related to fish weight, while various effects of the parasite on metal toxicokinetics and tissue-blood partitioning in the chub were accounted for in the model. In the model for infected chub, it was assumed that while taking up essential fatty acids, parasites absorb organo-metallic complexes formed between metals and bile acids excreted to the intestine. The model predictions show high tissue-blood partitioning in liver, attributed to the role of this organ as a detoxifying compartment. Assuming different effects of parasites on the uptake (enhancement) and elimination (alleviation) in the host, model predictions indicate increasing internal exchange between intestine, where the parasite resides, and other organs. Generally, the modelled concentrations of  $^{210}\text{Pb}$  were within one order of magnitude of the measured, for both infected and uninfected chub.

## **Addressing data collection and computational challenges in LCI (P)**

#### TH151

##### **The new Reviewer Registry of the European Platform on LCA**

S. Fazio, Institute for Environment and Sustainability; D. Pennington, European Commission

To support EU environmental policies based on Life Cycle approach, the European Commission hosts the “European Platform on Life Cycle Assessment (EPLCA).” The platform aims at providing coherent and quality-assured life cycle data, methods, and studies as well as information about developers and suppliers of LCA dedicated software and databases (DB), and service providers. The LCA Resources Directory (RD), aims to offer a sharing platform for information related to software and database developers/suppliers, and service providers within the LCA community, there is also a repository for studies and documents with specific templates allowing to upload studies on e.g. Product and Organisation Environmental Footprint, Ecodesign, EPD and related Category Rules/Criteria. Recently a new tool has been added to the Resource Directory, i.e. the Reviewer Registry, would provide a list of qualified (i.e. with different levels of compliance for Life Cycle based methods) reviewers from different countries/sectors. The Reviewer Registry is a tool designed to provide information about reviewers concerning their expertise, knowledge and other relevant info. It helps the users to identify potential appropriate reviewers for their LCA studies. Based on the info provided, the tool assigns a score (now based on International reference Life Cycle Data system (ILCD) handbook, and Environmental Footprint (EF) requirements). INFO PROVIDED: languages spoken, countries covered, Career info, education, list of employers, years of experience, number of reviews, Accreditation as third party reviewer, Attended courses, Review practice chair, Review practice trainer, sectors of work experience and years, etc. a searching tool has been also implemented, allowing the users to run specific queries, basing on the above mentioned meta-data.

#### TH152

##### **The application of PEF approach to the end-of-life of mechatronic products**

F. Reale, ENEA / LCA and Ecodesign Laboratory; P. Buttol, ENEA; M. Mengarelli; S. Scalbi, ENEA / LCA and Ecodesign Laboratory; A. Zamagni, Ecoinnovazione / LCA and Ecodesign Laboratory

The mechatronic sector is a strategic sector from the economic and environmental point of view, mainly due to the high content of strategic raw materials used such as (precious) metals, and also on the high production rate, short service life and, in turn, to the high waste flows they generate. The end-of-life (EoL) management of mechatronic products and the assessment of associated environmental impacts play thus a relevant role in the roadmap to resources efficient Europe, and several methods and approaches have been developed for dealing with it. Among these, the Product Environmental Footprint (PEF) methodology (1), currently being tested through pilot projects in different sectors, proposes a new EoL approach, which has raised the criticisms of many stakeholders in different sectors. This paper discusses main challenges and insights from the PEF EoL application to the case study of a domestic cooker hood, and attempts to answer the following questions: what kind of results are delivered by the PEF EoL approach in comparison with other approaches to EoL, such as the avoided impact approach? what are the main methodological and practical aspects arising in the application of PEF EoL approach to this sector/product group? The EoL formula proposed by the PEF has been applied to the EoL scenario of cooker hood component, namely the aluminium filter component and, results have been compared with results arising by the application of one of the most used approaches in the metal sector, i.e. the “avoided impact approach”. Environmental impacts delivered by PEF EoL approach is higher than environmental impacts delivered by the avoided impact approach. Main methodological/practical aspects arising from PEF EoL approach application to the studied product concern: 1) the definition of the recycled content; 2) the identification of disposal process to which recycled content of material has been diverted; 3) the definition of recycling fraction.

#### TH153

##### **Consistent allocation for co-production and recycling in LCA - A critical review of guidelines**

D.L. Schrijvers, The Life Cycle Group CyVi; G. Sonnemann, University of Bordeaux 1 / The Life Cycle Group CyVi

Recycling and co-product allocation have always been points of debate in Life Cycle Assessment (LCA). Several guidelines have proposed allocation procedures, but these recommendations are often divergent. We have reviewed allocation procedures of co-products and in recycling and recovery situations using a consistent and systematic approach, considering all material types and allowing for different LCA goals. The allocation methods that are most often used – allocation, the cut-off approach and substitution, which comprises the end-of-life recycling method, substitution for the recycled content and the 50/50 method – are mathematically compared to show how multiple recycling loops are considered and how the methods influence the LCA results. Based on the underlying values and assumptions of the methods a systematic framework is developed. A strict separation between attributional and consequential LCA related to different LCA goals is proposed for discussion, following the UNEP/SETAC Shonan definition of attributional LCA. This framework is used as basis for the critical review of recent guidelines regarding the consistency of their allocation procedures. Only the ILCD Handbook proposes a consistent approach in two of the four scenarios that are described. Often different approaches are recommended for co-products and recycled materials, although the boundary between these flows is not always clear. Many guidelines do not recognize the existence of different LCA goals, therefore elements of attributional and consequential LCA are often mixed, e.g. by recommending both the cut-off approach and the end-of-life recycling method. The market situation of the recycled material is not always taken into account, e.g. in the mandatory 50/50 method of the PEF Guide. Based on ISO/TS 14067 we propose a new substitution formula, replacing the arbitrary ratio of 50% by the market price ratio  $A$ . The main obstacles for consistent modelling are the different approaches for co-production and recycling and disregarding of different LCA goals and recycled material markets. We recommend to include material specific guidance in PCR documents on the determination of the avoided process, market price ratios, value-correction factors and relevant allocation criteria. The new substitution formula will be tested on case studies for organic chemistry and metals to show its applicability to credit for the recycling activity that actually leads to environmental benefits.

#### TH154

##### **Consistent allocation in LCA - Can avoided impacts be modelled in attributional LCA?**

D.L. Schrijvers, The Life Cycle Group CyVi; G. Sonnemann, University of Bordeaux 1 / The Life Cycle Group CyVi

LCA studies have recently been divided into attributional and consequential LCA. Each LCA approach serves a different goal definition and produces different types of results. It is therefore important that the LCA approach is consistently applied. Consistency is also very important for allocation in case of multifunctional products or processes, e.g. due to co-production or recycling. Avoiding allocation by substitution could be considered to be consequential by nature. However, in many studies and guidelines substitution is applied in attributional LCA as well. We identify two perspectives that condone this operation: 1) the contribution of the co-product to the environmental impacts of the product system is approximated by its conventional production process, which is used as *proxy* for the co-product – which reflects an allocation procedure, and 2) the avoided emissions of the conventional production process for the co-function are subtracted from the product

system, often referred to as *substitution, the avoided burden approach or system expansion*. Although both approaches give the same results, both perspectives are interesting topics for a discussion. Indicating one conventional process – or even a production mix – as the default production process for a certain (co-)product, i.e. in the proxy perspective, might disregard the potential of the multifunctional process to be an alternative production process that even could contribute to the production mix, for which its specific inventory could be determined. The definition of attributional LCA is relevant for the substitution perspective. “Describing the inputs and their associated emissions attributed to the delivery of a specified amount of the product functional unit” (PAS 2050) could leave room for applying substitution. However, if “the attributional approach attempts to provide information on what portion of global burdens can be associated with a product (and its life cycle)” (UNEP/SETAC, 2011), substitution might result into losing impacts between product systems, as Heijungs already argued in his PhD thesis (1997). As both definitions can facilitate relevant LCA studies, e.g. for comparing products, we recommend to clearly distinguish between LCA purposes and these definitions, for consistent application of allocation procedures.

#### TH155

##### **Assistox: A data management tool for the calculation of toxicity characterization factors**

G. Rodríguez García, Helmholtz Institute Ulm / Systems III; M. Weil, Karlsruhe Institute of Technology KIT / Institute for Technology Assessment and Systems Analysis ITAS

In Life Cycle Assessment (LCA) studies, toxicity impact assessment categories are often not included or discussed in depth. Two possible reasons for that are: a) the perception that they are a black box and less reliable than other impact categories, and b) the lack of characterization factors (CF) for potentially key pollutants. We have developed Assistox, a tool to facilitate the calculation of CF with USEtox impact assessment methodology. It consists of two main components: s) a detailed procedure that guides LCA practitioners through data made available by the European REACH regulation and other freely-available databases, and b) an Excel spreadsheet that transforms collected information into ready-to-export data for the aforementioned methodologies. The ongoing validation process suggests that the differences between the CFs calculated using Assistox and those already available for USEtox are not statistically significant for Freshwater Ecotoxicity and for Human Toxicity in most emission compartments. These results indicate it would be possible to obtain compatible CF for new substances. It is our opinion that tools like Assistox can make toxicity impact categories more accessible, and will foster the use of these categories in future LCA studies.

#### TH156

##### **Results of the ERASM Surfactant Life Cycle and Ecofootprinting (SLE) project: New and updated inventory data for oleochemical and petrochemical surfactants**

K. Groenke, Evonik Industries AG / Department ESH; A. Bouvy, Cefic; D. Eggers, PE International AG; E. SLE Task-Force, ERASM

The objective of the SLE project was to update and establish the environmental profile of the major commercial surfactants and their precursors in Europe based on consistent and high quality (background) data. Fifteen companies collaborating within ERASM ([www.erasm.org](http://www.erasm.org)) compiled ‘cradle-to-gate’ life cycle inventories (LCIs) data for state of the art production of a series of common surfactants used in detergents and personal care products. The intention of the environmental profiles is to support the increasing use of LCA in industry as well as in various policy initiatives and provide data for ‘cradle-to-grave’ assessments of consumer products. For each major unit process in the surfactant production at least three companies (‘trios’) were identified, which confidentially provided process data to the project’s independent consultant, hence allowing to produce an aggregated anonymous average. Literature data were used where it was difficult to collect new data within the scope of this project, or in case recent and reliable process data were available. The LCI methodology was compliant to the international LCA standards ISO 14040:2006 and ISO 14044:2006. Two independent external reviewers, focusing primarily on LCA methodology conformity and process technology, supported the project from the beginning through completion. In addition, the data for palm (kernel) oil-, coconut oil- and tallow-based renewable precursors were reviewed by a third expert who was a specialist in the matter. The ERASM SLE project has delivered new and updated LCI data for 15 surfactants and 22 precursors in three common LCI exchange formats: ILCD, EcoSpold v.2 and GaBi. The data reported represent an industry-agreed and representative market average for surfactants in European consumer products for the reference year 2011. Similarities and differences with the previously published surfactant LCI data (1995) are discussed, as well as the novel approach to calculate the greenhouse gas emissions resulting from land use changes in Malaysia and Indonesia associated with the cultivation of renewable precursors.

#### TH157

##### **National Level LCA of Potable Water Supply System - Key Challenges and Solutions in Data Collection**

N. Meron, The Porter School of Environmental Studies; V. Blass, Tel-Aviv University / The Recanati Graduate School of Business Administration  
This study generates Israel's LCI dataset of tap water and reclaimed water. For

many years severe water scarcity in Israel has been a driver for the development of advanced water technologies. High quality water supply throughout the entire country has been made possible through a vast and complex water supply system. The contribution of the Israeli advanced water supply system to past and present development of agriculture and industry have been studied in detail. Less known is the associated environmental impact of the Israeli water system, an issue of growing importance as the protection of environment and the reduction of environmental impact become a central theme in decision making. Our research on the LCI dataset of tap water in Israel covers the entire value chain of the country's highly complex water supply system. It includes: water extraction and production from a variety of sources such as groundwater, surface water, brackish water and sea water; water treatment; desalination; a national transmission system, which runs throughout the entire country; distribution and tertiary treatment of wastewater for water reclamation. The study comprises data collection for all components of the Israeli water system, resulting in the first national level LCI of tap water. To carry out a national level study there was a need to collect data from a wide array of sources, public and private. The collected data is related to energy and chemical consumption, materials for infrastructure, and transportation of materials. The data collection process introduced major challenges such as: difficulties of access to data sources, in particular private data sources, limited availability of old data and non-aggregated data, and incompatibility of data from various sources. Our approach to resolve these challenges included stakeholder engagement and data processing. The study used the ReCiPe method to assess the impacts of the system on climate change, water depletion, freshwater and marine water eutrophication, freshwater and marine aquatic ecotoxicity, and terrestrial and water acidification.

#### TH158

##### **Life cycle inventory of a new process employing rice husk ash for the inertization of air pollution control residues coming from MSWI**

G. Tomasoni, Università degli Studi di Brescia / Department of Mechanical and Industrial Engineering; I. Barberá Franch, University of Brescia / Department of Mechanical and Industrial Engineering; M. Collotta, University of Brescia; M. Alberti, University of Brescia / Department of Mechanical and Industrial Engineering

In this work the methodology and the main results of the Life Cycle Inventory phase (LCI) of the Life Cycle Assessment (LCA) of the Cosmos-rice process are presented. Cosmos-rice is a new process for the inertization of air pollution control residues coming from Municipal Solid Waste Incineration (MSWI). The inertization process, which has been developed by the Chem4Tech laboratory of the University of Brescia, uses as stabilizing agent rice husk ash. The LCI analysis conducted over a new technology bears some problems, due, for example, to the lack of primary data (i.e. data gathered on the field) or to the lack of consistency of secondary data (i.e. data taken from literature and databases) with respect to the data quality requirements. Of great interest for the LCI of the Cosmos-rice process is the availability as a source of primary data of a pilot plant for the inertization which was designed and built thanks to a project funded by the European Union through the Life+ program (LIFE11 ENV/IT/0000256). The role of a pilot plant seems to be very important to gather data from the field and to conduct a reliable life cycle inventory phase, even though some limitations related to this approach emerge.

#### TH159

##### **Database selection - be aware of the implications!**

L. Golsteijn, PRE Consultants; T. Ponsioen, PRE Consultants / Consultancy OBJECTIVES In LCA software, multiple inventory databases are available that can be used for background processes in an LCA. The way the emissions and resource extractions in the background data are modelled can be of crucial importance for the results of a product life cycle assessment. The question is whether the influence of this modelling approach matches the goal and scope of the LCA study. This poster demonstrates the potential impact of differences in the modelling approach of the background data. METHODS We selected 7 products from different sectors, present in multiple databases ( $\geq 2$  of the following databases: ELCD, USLCI, Agri-footprint, ecoinvent 2.2, ecoinvent 3.1 cut-off), and compared their impact with 2 different methods in SimaPro 8.0.4: ReCiPe Endpoint (H) and IMPACT2002+. RESULTS The following categories showed large differences between databases in several cases: Climate change: we observed important differences due to differences in the input-output balance, especially in case of crop products. Natural land transformation: we observed extreme differences due to the modelling approach chosen in the database for crops that are grown in the tropics. Toxicity: we observed important differences in flows of metals to the soil which can be positive (emission) or negative (take up), as well as differences in the presence or absence of substances and the accompanying quantities. Particulate matter formation: we observed important differences in the level of detail of the inventory data (particle size) and assumptions on ammonia emissions from the soil. It is important to note that differences between databases will not always be visible in the output; this depends on the selected method. CONCLUSIONS When conducting an LCA with background LCI data, the results can be influenced significantly by assumptions and/or shortcomings of the selected database, particularly for climate change, natural land transformation, toxicity, and particulate matter formation. This study emphasizes the importance of selecting a second method to reveal ‘potentially hidden impacts’. We recommend to check

whether the modelling approach of the background data matches the goal and scope. Future research should include the development of more alternative inventory databases, in order to reveal shortcomings and hidden assumptions of LCI databases and to enable practitioners to select the database that best matches the goal and scope of their LCA.

#### TH160

##### **Modular, parameterized life cycle inventories of transport of goods in need of atmosphere control**

T. Levova; E. Moreno Ruiz, ecoinvent; G. Bourgault, Ecoinvent Center

Nowadays, when goods are being traded all over the world on an increasing scale, the significance of the freight transport within the overall environmental impacts of product supply chain is increasing as well. While some goods do not need specific conditions during their transport, others, such as food, need to be stored and transported while maintaining certain atmosphere (temperature, air flow, etc.). The atmosphere control, of course, requires specific infrastructure and energy for the operation of the infrastructure. This project focus on creation of datasets, using different sources of information - such as publically available databases - and the latest LCI modelling options available thanks to the use of ecoSpold2 format. The datasets on the undefined unit process level are built so that the modelling is transparent, easily adaptable, well documented and it is possible to demonstrate the differences in the modelling using the three different system models currently offered by the ecoinvent database. The life cycle inventories are built in ecoSpold2 format using variable names, mathematical relations and parameters. All datasets are parameterized, allowing flexibility to adjust key parameters of the whole system such as type of goods, refrigerant, distance and duration of transport, etc. The preliminary results, using IPCC 2007, 100a method, demonstrate that the final impact of a product might be increased by around 9% when transport with atmosphere control is included. This corresponds with values published in other studies. This value might vary significantly in specific cases and further research is needed produce more reliable value for different type of goods.

#### TH161

##### **Simplified modelling of environmental impacts of foods**

F. PERNOLLET, INRA, UMR SAS / UMR SAS; H.M. van der Werf, INRA, UMR SAS / Environnement et Agronomie

Human nutrition strongly contributes to several environmental impacts, resulting in more and more LCA studies on foods and diets. However these studies highlight a lack of data on food products. As a result, these studies make huge simplifications, such as reducing the number of foods considered, using a proxy to model a group of foods, modelling only the stage up to the farm gate or to the retailer instead of the full life cycle, or considering only the climate change impact. These simplifications can strongly affect the results. This study proposes three methods to simplify impact assessment of food products, considering time available and required robustness of results. The first method is based on the fact that, for a food product, most of the impact is often due to the farm stage, for which data are often available or can be estimated relatively easily. The impact of the food product can then be estimated by considering the allocation and transformation coefficient at industry, and waste at retailer and at home. The second method improves the first method by adding cooking impacts, and the third method adds transport impacts. The three methods were tested on a French average diet for the impacts climate change, cumulative energy demand (CED), acidification, eutrophication and land occupation and results were compared to those of a detailed cradle to plate LCA of this diet. Except for CED, and relative to the detailed LCA, the three methods yielded a better estimate than a detailed cradle to retailer LCA. Compared to the detailed LCA, the underestimations (in %) obtained with methods 1 and 3 were respectively (24, 60, 10, 9, 8) and (12, 30, 5, 6, 8) for climate change, cumulative energy demand, acidification, eutrophication and land occupation. Methods 1, 2, 3 and the detailed cradle to plate LCA are increasingly time-consuming. Method 1 is adapted for products with a high cradle to farm impact such as dairy and meat products. Method 3 is adapted for fruit, vegetables, pulses, dairy and meat products, but is too imprecise for products with high-impact packaging (can and glass), or for products with a high energy demand during industrial transformation such as coffee, semolina, ultra-high temperature milk. These methods should be tested on more diet types and for more impacts for validation.

#### TH162

##### **RELCA a case study approach for assessing bioenergy chains on a regional level**

S. O'Keefe, Helmholtz centre for environmental research - UFZ / BEN; S. Majer, DBFZ Deutsches Biomasseforschungszentrum gemeinnützige GmbH DBFZ / BS; D. Thraen, Helmholtz Centre for Environmental Research - UFZ / BEN

For well over a decade, the energy conversion systems have been shifting from globalised scales to more regional and decentralised scales in the form of biomass-to-bioenergy chains. Unlike its fossil counterpart, biomass is scattered in a diffuse manner across a region. Therefore, in order to identify the potential environmental burdens associated with regional bioenergy production, the spatial configurations of bioenergy chains and thus the related regional conditions need to be assessed. The LCA approach for regional bioenergy systems, or RELCA, was applied to the Central Germany region. The RELCA approach expands on traditional life cycle methods, using a "hybrid" life cycle inventory approach, as it

involves integrating the results of different modelling approaches, ESRI ArcGIS<sup>®</sup>, Matlab and LCA tools (GABI 6.0). The combination of these modelling approaches enables the assessment of spatially disaggregated foreground data at the regional level for biomass-to-bioenergy production chains, while also linking to background processes. Background processes, or non-regional processes, in this case refers to all those activities outside the regional scope. In making this separation, the foreground data can then be coupled with other modelling approaches in order to generate a more regionally distributed life cycle inventory.

## **Endocrine Disruptors: Exposure, Hazard & Risk Assessment (P)**

#### TH163

##### **Recent global regulatory developments and data requirements for endocrine disruptor testing and assessment**

M. Duft, DR. KNOELL CONSULT GmbH / ICEHSECOM; I. Conrad, DR.

KNOELL CONSULT GmbH / Agrochemicals Ecotoxicology

Despite decades of scientific research and extensive discussions and work within regulatory panels, an intended consensus on the assessment of substances with an endocrine disrupting potential, so-called endocrine disruptors, has not yet been reached or is not even conceivable in the near future. Several diverging proposals for an assessment of plant protection products or biocidal products to consider potential endocrine effects are available within the European Union, e.g. by Denmark, UK/Germany or France. Under REACH, substances with endocrine disrupting potential can be considered as substances of very high concern and may be subject to authorization. Whereas the European proposals are mostly aiming at a hazard-based assessment proposing endocrine disrupting properties as cut-off criterion with few exceptions, US EPA follows a different approach and pursues a comprehensive two-tiered screening program still to be followed by risk-based assessment. In other areas of the world, e.g. Canada, Brazil, China, Japan or Korea, national programs for the assessment of endocrine disrupting chemicals have been launched or are about to follow other proposals. As scientific criteria for the evaluation of endocrine disrupting properties of a substance are still not yet available, assessment is mostly conducted on a case-by-case basis at the moment. For companies intending or supporting global registrations for their substances, this results in substantial uncertainty regarding data requirements or testing and assessment strategies. This presentation aims to give a global overview on present regulatory proposals, recent regulatory developments and data requirements for the assessment of endocrine disrupting chemicals.

#### TH164

##### **An Analysis of Control Data from the US Endocrine Disruptor Screening Program List 1 Chemical Screening Battery Results**

A. Schapaugh, Monsanto Company; L. McFadden, The Dow Chemical Company / Toxicology Environmental Research and Consulting; J.W. Green, DuPont / Applied Statistics Group; L. Zorrilla, Bayer CropScience LP; A.W. Olmstead, Bayer CropScience / Environmental Toxicology and Risk Assessment; C. Borgert, Applied Pharmacology & Toxicology, Inc.; S. Hicks, ABC Laboratories; H.O. Krueger, Wildlife International, Ltd. / Aquatic Toxicology

US EPA's Endocrine Disruptor Screening Program (EDSP) Tier 1 battery consists of five *in vitro* and six *in vivo* assays intended to identify the potential of a chemical to interact with the estrogen, androgen, or thyroid hormone systems and the steroidogenesis pathway. Following a recommendation to initially screen 50-100 substances, EPA has elected to proceed in phases, with the first phase composed of 67 chemicals (hereafter, List 1). We have collected data for control groups from a subset of the assay results submitted to EPA. The purpose of this paper is to use this information in a critical investigation of the data variability and performance criteria of the EDSP Tier 1 battery. The analysis demonstrates that EPA should review all testing methods prior to issuing further test orders. Given the frequency with which certain performance criteria were not met (e.g., all male pubertal studies had at least one performance criteria that was not met), one focus of that review should consider adjustments to these standards to better reflect biological reality. Poorly-defined criteria will result in discarded data and wasted resources. A second focus of the review should be to provide detailed, assay-specific direction on when results should be discarded; no guidance exists on the degree to which assays need to be re-started for failing to meet performance criteria. A third focus of the review should be to identify protocol differences with a large influence on endpoint variance. After identification of these influential factors, experimental guidelines could be re-defined such that endpoint variances are reduced and performance criteria are met more frequently. It must be emphasized that because we were restricted to a subset of the List 1 control data, our analyses can serve only as examples to underscore the importance of a detailed, rigorous, and comprehensive evaluation of the performance of the battery.

#### TH165

##### **An integrated assessment of estrogenicity of complex environmental samples using *in vivo* and *in vitro* effect-based tools**

S. Hélène, Université Paris Descartes / Faculté des sciences pharmaceutiques et biologiques; F. Brion, INERIS / Ecotoxicology Unit; N. Creusot, INERIS; J. Porcher, INERIS / UMRI SEBIO; N. Munz, Eawag; J. Hollender, Eawag /

Environmental Chemistry; T. Schulze, M. Krauss, W. Brack, Helmholtz Centre for Environmental Research UFZ / Effect Directed Analysis; S. Ait-Aissa, INERIS / Ecotoxicology Unit

Assessing the risk posed by complex environmental samples is a challenging task that requires reliable tools for detection and evaluation of effects. Among hazardous compounds, endocrine disrupting chemicals (EDC) in mixtures need to be identified given their potential to interfere with wild life reproduction. In this context, the aim of our work is to apply a set of effect-based tools, both *in vivo* and *in vitro*, to environmental samples in order to gain a wide overview of adverse outcomes related to estrogenic pathways in fish. As part of the FP7-SOLUTIONS project, we screened surface water extracts of Danube River (22 sites) and extracts of Rhine tributaries (water extracts of 3 STP effluents, upstream, and downstream sites in Switzerland) using an *in vitro* human ER reporter system (MELN cell line). Additionally, Rhine tributaries extracts were assessed *in vivo* for induction of *CYP19a1b* gene, which is strictly ER-regulated, in transgenic zebrafish embryos (EASZY test). Results obtained so far with the MELN assay show very low estradiol-equivalents (E2-EQ) levels at Danube sites (only 3 sites displaying E2-EQ above 0.1 ng/L), while slightly higher estrogenic activity was measured at Swiss sites (E2-EQ ranged from 2.9-5.5 ng/L in effluents, and 0.1-0.3 and 0.5-1.5 at upstream and downstream sites, respectively). The estrogenic activity detected *in vitro* in effluents was correlated to estrogenicity *in vivo* for one site, based on *CYP19a1b* induction; the other effluents displayed developmental toxicity which impeded reporter gene activation detection. To gather further information on estrogenicity of these samples, work is under progress to assess their effects on zebrafish (zf) cell lines stably transfected with zebrafish estrogen receptors (i.e. zFERalpha, zFERbeta1 and zFERbeta2). Results will be interpreted in relation to targeted chemical analyses done at these sites. Eventually, the study should provide a comprehensive assessment of estrogenicity of given environmental samples using a combination of mammalian and zebrafish cell lines, as well as an *in vivo* fish embryo bioassay. *This study is supported by INERIS and by SOLUTIONS Project from the European Union Seventh Framework Programme (FP7-ENV-2013-two-stage Collaborative project) under grant agreement 603437.*

#### TH166

##### **Development of the OECD Mollusc reproduction guideline: Do Trenbolone and Prochloraz have any effect on *Potamopyrgus antipodarum* reproduction?**

C.E. Askem, Cefas / Ecotoxicology; D. Doran, C. Martin, T. McGowan, Cefas Lowestoft Laboratory; M. Vannoni, Cefas; T. Wilkinson, Cefas Lowestoft Laboratory; K. Ruppert, Goethe Universität / Aquatic Ecotoxicology; C. Geiss, Goethe University Frankfurt; J. Oehlmann, Johann Wolfgang Goethe-Universität Frankfurt / Aquatic Ecotoxicology; J. Elphinstone Davis, Cefas Weymouth

In 2010 a need for an OECD test guideline on mollusc reproduction was identified in a detailed review paper. Currently this is under development using two different mollusc species and various validation tests by a number of laboratories around the world are being conducted. One of the species is *Potamopyrgus antipodarum* (mud snail) and as part of the validation testing Cefas took part in a ring trial using Trenbolone and Prochloraz to see if they had any effects on the reproduction of *P. antipodarum*. Trenbolone is a veterinary steroid used to increase livestock muscle mass and has been shown to have effects on reproductive endpoints in other species. Prochloraz is an imidazole fungicide used in gardening and agriculture and has also been shown to have disruptive effects on reproductive endpoints. The use of these chemicals, which are known to have reproductive effects in other species, provides valuable data for the development of the test guideline. This study used concentrations of Trenbolone ranging from 0.01 to 1 µg/L and Prochloraz ranging from 3.2 to 320 µg/L. The endpoint is the number of embryos in the brood pouch of the snails after 28 days exposure. Trenbolone did not have any significant effect on embryo numbers compared to the control. Whereas for Prochloraz the EC<sub>50</sub> for number of embryos, based on nominal concentrations, was 175 µg/L (95% Confidence limits 127 µg/L to 242 µg/L) with an EC<sub>10</sub> at 34.9 µg/L (95% Confidence limits 12.1 µg/L to 101 µg/L). The NOEC was < 3.2 µg/L and LOEC was 3.2 µg/L. This data will contribute to the full ring study which is being coordinated by Johann Wolfgang Goethe University Frankfurt, Germany.

#### TH167

##### **Triclosan and endocrine disrupting potential: An hypothesis-driven weight of evidence analysis**

E.M. Mihaich, ER2; R. Hartsook, D. Urbach-Ross, Colgate-Palmolive Company

Triclosan (TCS) is an antimicrobial agent used in a wide range of personal care and consumer products, such as soaps, deodorants, cosmetics, dental care, clothing and household items. As with most personal care products, TCS can be rinsed down the drain and transported to wastewater treatment plants. While TCS is biodegraded and can sorb to biosolids, some TCS enters the aquatic environment and may expose ecological receptors. Given the potential for exposure to both humans and wildlife, resolving whether or not TCS should be considered a potentially endocrine active compound is important given increasing worldwide concern about endocrine disrupting substances and their potential for causing adverse effects on public health and the environment. A weight-of-evidence (WoE) analysis was conducted, focusing on specific hypotheses related to interaction with estrogen, androgen, and thyroid hormone pathways, and steroidogenesis. This WoE procedure involved systematic consideration of each endpoint observed in one or more study designs, focused on the screening level studies in the US Endocrine Disruptor Screening

Program, as well as those in levels 1 through 4 of the OECD Conceptual Framework. This was followed by a semi-quantitative weighting of relevance of each type of endpoint to a given hypothesis to reach scientifically justified conclusions based on the totality of the evidence. Maximal use of all existing relevant and reliable information and consistent observations in multiple studies increase support for or against a given mode of action (MoA) hypothesis. While the TCS database continues to grow and its evaluation is ongoing, a systematic and transparent WoE assessment of the results from a wide variety of mammals, fish, and amphibians suggest that TCS is not primarily impacting endocrine pathways.

#### TH168

##### **Selection and use of carrier solvents for OECD test guideline development with mollusc species**

J. Elphinstone-Davis, Cefas; C. Veauvy, Cefas / Environment Animal Health; S. Morris, Cefas; K. Ruppert, Goethe Universität / Aquatic Ecotoxicology; C. Geiss, Goethe University Frankfurt; J. Oehlmann, Johann Wolfgang Goethe-Universität Frankfurt / Aquatic Ecotoxicology; M. Roberts, Department for Environmental Food & Rural Affairs / Chemicals Emerging Technologies; C.E. Askem, Cefas / Ecotoxicology; A. Barsi, INRA and VU University Amsterdam / Dept of Theoretical Biology; V. Ducrot, Bayer CropScience AG / Ecotoxicology and Quality of Aquatic Ecosystems; T. Hutchinson, School of Biological Sciences, Plymouth University

The OECD has successfully developed a range of test guidelines for detecting reproductive (including endocrine disruption) impacts in mammals, fish, amphibians and arthropods. An OECD (2010) Detailed Review Paper concluded that there is a need to include and develop guidelines to address reproductive toxicological impacts of chemicals on molluscs, given their major ecological and economic importance and known sensitivity to a number of chemicals (including EDCs). An *ad hoc* European expert group was established to validate draft guideline methods that aim to meet this need. Key species for use in this context are the freshwater gastropods *Lymnaea stagnalis* and *Potamopyrgus antipodarum*. Test chemicals required for future evaluation of this draft OECD molluscan test guideline will require the use of carrier solvents. The OECD recommends a list of solvents to use when test substances are not readily soluble in the test media. We have tested two of these solvents, methanol and triethylene glycol (TEG) for their effect on the growth and reproduction of *L. stagnalis* (RENILYS® strain) at nominal concentrations of 12.5, 2.5, 1.0, 0.5 and 0.02 mL/L over 35 days, and report here the results. The test followed the requirements of the draft guideline under evaluation by the OECD. Overall, TEG and methanol had no significant effect on *L. stagnalis* survival, growth and reproduction below the 0.1 mL/L threshold recommended by the OECD: with a NOEC for TEG and methanol of 12.5 and 0.5 mL/L respectively. We additionally report on 35 day *L. Stagnalis* studies conducted at INRA, France. To compare the results with the impacts of solvents on the embryo-larval stages of molluscs, a developmental toxicity embryo bioassay was conducted with *Crassostrea gigas*. Solvents tested came from the recommended OECD list: acetone, dimethylsulfoxide (DMSO), ethanol, glacial acetic acid, methanol, and TEG, tested at the above nominal concentrations, over 48 hours at 20 ± 2°C. All solvents, except glacial acetic acid, had a developmental NOEC of ≥ 2.5 mL/L. We are currently augmenting this data set with *P. antipodarum* exposure studies; early results indicate no effect of DMSO below the 0.02 mL/L threshold suggested by Hutchinson *et al* (2006). These results provide an important contribution to developing laboratory baseline data for growth and reproduction of *L. stagnalis* and *P. antipodarum* for future validation work of the OECD mollusc reproductive toxicity test guideline.

#### TH169

##### **Thyroid disruption in developing zebrafish (*Danio rerio*) embryos - effects on gene-expression and morphology**

L.A. Baumann, University of Bern / Centre for Fish and Wildlife Health; K. Rehberger, University of Bern / FiWi; H. Segner, University of Bern / Centre for Fish and Wildlife Health

Environmental contaminants with endocrine disrupting properties are not only able to disrupt the reproductive system of fish, but also their thyroid system. Comparably little is known about the developmental, physiological and behavioral consequences of thyroid disruption in fish. As the thyroid system plays an important role in key physiological processes such as growth, development and reproduction, its environmentally induced disruption can impact a variety of health and fitness-related parameters such as larval survival, metamorphosis, behavior or fertility. These organism-level changes can then propagate into altered population demography due to selective mortality. Consequently, there is urgent need for more intensive research on the effects of thyroid disruption in fish. The present study aims to investigate the relation between initiating molecular events of thyroid disruption and morphological changes of the embryonic development of zebrafish (*Danio rerio*). Two modes of action were studied: interference with thyroid hormone synthesis with the pharmaceutical Propylthiouracil (PTU), and binding to thyroid hormone receptors with the flame retardant Tetrabromobisphenol A. Changes in gene-expression were analyzed with qRT-PCR and visualized with whole mount *in situ* hybridization. The morphological changes were assessed by means of histologic and morphometric analyses. The results provide initial insight if and how chemical interactions with molecular events in the thyroid axis of zebrafish translate into morphological alterations of the developing embryos.

#### TH170

##### **Synthetic glucocorticoids in the aquatic environment: effects on zebrafish (*Danio rerio*) embryos**

A.O. Hidasi, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology; K.J. Groh, Eawag / UTOX Environmental Toxicology; M.J. Suter, Eawag - Swiss federal Institute of Aquatic Science and Technology / Environmental Toxicology; K. Schirmer, Eawag / Environmental Toxicology  
Synthetic glucocorticoids (GCs) are frequently used in medicine. These compounds were detected in the aquatic environment in the ng/L range. GCs mimic cortisol, the natural stress hormone, by acting through the glucocorticoid receptor (GR) and altering target gene expression. Endogenously, cortisol is produced in fish when the hypothalamus-pituitary-interrenal (HPI) axis is activated. In our work, zebrafish embryos are used to investigate whether exposure to environmentally relevant concentrations of a model GC, clobetasol propionate (CP), results in GC-related effects, such as impairment of the stress response and immunosuppression. We avoid using an organic solvent carrier, such as DMSO, due to the experienced solvent effects. We are focusing on nanomolar concentrations, and since CP can be dissolved in the embryo medium up to 1000 nM, no precipitation is expected. Zebrafish embryos are exposed from 1-96 hours post fertilization (hpf). In order to investigate the effect of CP exposure on the stress response, the cortisol level of non-stressed and stressed embryos is measured by ELISA. Bacterial (*Pseudomonas aeruginosa*) lipopolysaccharide (LPS) challenge assay is used to assess the effects of CP exposure on the innate immune function in 4 days post fertilization (dpf) embryos after exposed to CP from 1 hpf. The time course of survival is monitored after LPS addition. Targeted proteomics analyses are conducted on tryptic peptide digests of embryos exposed to 10 or 100 nM CP from 96-120 hpf. The proteotypic peptide targets are monitored using a mass-spectrometry based targeted proteomics technique, selected reaction monitoring (SRM). GR target genes already examined in zebrafish at the mRNA level were selected to monitor their protein products. The targeted proteins have different physiological roles, e. g. myogenesis, vitamin D metabolism, immune function, and cardiogenesis. The described work characterizes the CP effects on the physiological and molecular levels. Impairment of the stress response and immunosuppression can reduce the fitness of fish in the environment, thus GCs, such as CP, should be monitored. The targeted proteomics part of this study is focusing on finding potential GC-specific and sensitive biomarkers that can be used in developing a bioassay to monitor GCs in water samples. The bioassay will be used in effect-directed analysis (EDA) in order to identify unknown compounds able to interfere with the HPI axis.

#### TH171

##### **Thyroid disruption by triphenyl phosphate, an organophosphate flame retardant, in zebrafish (*Danio rerio*) embryos/larvae and two cell lines**

S. Kim, J. Jung, Seoul National University / School of Public Health; I. Lee; D. Jung, Seoul National School / Institute of Health and Environment; H. Youn, Seoul National University; K. Choi, Seoul National University / School of Public Health  
Triphenyl phosphate (TPP) is one of the most widely used organophosphate flame retardants (OPFRs). Although TPP has frequently been detected in the environment and biota, current knowledge on its toxicological effects is limited. The present study was conducted to understand adverse impacts of TPP on the thyroid hormone system and underlying mechanisms, using early life stage of zebrafish and two cell lines, i.e., rat pituitary (GH3) and thyroid follicular (FRTL-5) cells. In the GH3 cells, TPP up-regulated the transcription of *tsh $\beta$* , *tra*, and *tr $\beta$*  genes while a positive control T3 showed the opposite direction of change. In FRTL-5 cells, exposure to TPP led to significant up-regulation of the *nis* and *tpo* genes, suggesting that TPP stimulates thyroid hormone synthesis in the thyroid gland. In zebrafish larvae, TPP significantly increased the levels of both T3 and T4 and transcription of the genes involved in thyroid hormone synthesis, at 7 days post-fertilization (dpf). Exposure to TPP also led to significant up-regulation of the genes involved in the transport (*ttt*), metabolism (*dio1*), and elimination (*ugt1a*) of thyroid hormones in zebrafish larvae. The down-regulation of the *crh* and *tsh $\beta$*  genes suggests that the increased T3 levels activate a central regulatory feedback mechanism *in vivo*. In conclusion, our observations show that TPP could increase the thyroid hormone levels in the early life stages of zebrafish by influencing the central regulation and hormone synthesis pathways.

#### TH172

##### **In vitro assessment of thyroidal, estrogenic and androgenic activities in poultry and broiler manure**

A. Valdehita, Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria (INIA) / Departamento de Medio Ambiente Lab DETC; A. Quesada-García, INIA; E. Becerra, Universidad Complutense de Madrid; M. Delgado, J. Martín, INIA National Institute for Agricultural and Food Research and Technology; M. García-González, ITACyL; M. Fernández Cruz, Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria (INIA) / Departamento de Medio Ambiente Lab DETC; J. Navas, INIA - Madrid  
Animal waste from livestock farming can contain natural and synthetic hormones. The use of this manure to fertilize agricultural land could contaminate surrounding waterways affecting aquatic organisms. While most research in this field has focused on estrogenic and androgenic phenomena, little is known about alterations related to other endocrine systems, such as the thyroidal one. Here we

simultaneously assessed the potential estrogenic, androgenic and thyroidal activity of poultry and broiler manure using in vitro approaches based on estrogen receptor (Er), androgen receptor (Ar) and thyroid receptor (Tr) transactivation assays. In addition, leaching experiments were performed to assess whether endocrine activities detected in manure could pass through a soil column and potentially reach the groundwater. For that, columns with two kinds of arable soils, sandy and loamy, were used. Manure from four broiler and four poultry farms was collected in two sampling campaigns carried out in two seasons (fall and spring). Extracts from broiler and poultry manure exhibited strong thyroidal activity. However, as expected taking into consideration sex and developmental stage, estrogenic activity was only present in poultry manure and androgenicity was detected only in broiler extracts. After leakage experiments, no estrogenicity, androgenicity or thyroidal activity was detectable in leachates or in soils treated with the manure. These results indicate that substances responsible of the hormonal activities were degraded or metabolized in soil. Further research is required to elucidate long-term effects associated with the constant and intensive application of manure to agricultural land.

#### TH173

##### **Estrogenicity of environmentally relevant chemical mixtures is not predicted by ethinyl estradiol**

H. Yu, C.M. Johnson, Temple University / NSF WET Center; D.J. Caldwell, Johnson & Johnson; R.P. Suri, Temple University / NSF WET Center  
Endocrine active compounds (EACs) comprise a wide range of natural and synthetic estrogen hormones, pharmaceuticals, pesticides and industrial chemicals, which may alter the function of endocrine systems and consequently cause adverse effects in wildlife and humans. The presence of EACs in wastewater, surface water, groundwater and even drinking water has become a major public concern worldwide. Exposure to a mixture of EACs has been predicted to result in additive effects, but this has not been studied using environmentally relevant mixtures of EACs. In this study, the estrogenic effects of 11 EACs of high environmental concern were systematically investigated using the yeast estrogen screen (YES) method. The contribution of individual chemicals to the total endocrine activity of environmentally relevant mixtures was evaluated. 17 $\beta$ -estradiol (E2) was used as positive control on each plate in the YES assay. Bisphenol-A (BPA), estrone (E1), estriol (E3), ethinyl estradiol (EE2), and genistein (GEN) showed estrogenic activity when compared with E2; Bis(2-ethylhexyl) phthalate (DEHP), octyl phenol (OP), nonyl phenol (NP), Benzyl butyl phthalate (BBP), and Dibutyl phthalate (DBP) showed anti-estrogenic activity. The full mixture of all these chemicals at an environmentally relevant ratio also showed weak anti-estrogenic activity. Further, EE2 did not have a prominent contribution to the estrogenic activity of the mixture. We conclude a holistic evaluation of the estrogenic activity is necessary to evaluate the risk of a mixture of EACs.

#### TH174

##### **Does dissolved organic carbon cause apparent antagonism in reporter gene assays?**

P.A. Neale, Griffith University / Smart Water Research Centre; B.I. Escher, Helmholtz Centre for Environmental Research GmbH - UFZ / Cell Toxicology; F.D. Leusch, Griffith University - Smart Water Research Centre / School of Environment and Smart Water Research Centre  
There is increasing awareness of the importance of assessing antagonism in parallel with agonism for environmental samples, such as wastewater, as a number of studies have observed both estrogenic and anti-estrogenic effects when using cell-based bioassays. Some studies have attributed this to the presence of dissolved organic carbon (DOC), which is found in surface waters and wastewater and can be co-extracted during sample enrichment prior to bioanalysis. DOC has a high sorption capacity for the estrogen receptor (ER) agonist 17 $\beta$ -estradiol, which may reduce the 17 $\beta$ -estradiol free concentration used in the antagonist testing mode and potentially lead to apparent antagonism. This study applied an experimental and modelling approach to assess the influence of DOC when assessing antagonism using an ER reporter gene assay. Humic acid and fulvic acid were used as reference DOC and experimental DOC-water partition coefficients ( $K_{DOC}$ ) were used to predict 17 $\beta$ -estradiol binding to DOC. GeneBLAzer® ER $\alpha$ -UAS-bla assay was used and experiments were conducted with standard curves of 17 $\beta$ -estradiol with humic acid and fulvic acid added at concentrations expected to cause 20 to 60% binding to 17 $\beta$ -estradiol. The experimental results were compared with the modelled reduced 17 $\beta$ -estradiol bioavailability based on experimental  $K_{DOC}$  values. Both the experimental and modelled results showed that DOC does have an influence on the free 17 $\beta$ -estradiol concentration, increasing the EC<sub>50</sub> value by around 0.3 log units. The experimental and predicted EC<sub>50</sub> values were close, within 0.2 log units of each other on average. However, the observed changes with DOC were within the variability associated with the DOC-free 17 $\beta$ -estradiol standard curve. Consequently, we conclude that the presence of DOC is unlikely to cause significant experimental artefacts when assessing ER antagonism *in vitro*.

#### TH175

##### **MARINAS AS SOURCE OF FRESH TBT IN SOUTH AMERICA**

I.B. Castro, Universidade Federal de São Paulo / Instituto do Mar; G. Fillmann, Universidade Federal do Rio Grande / Institute of Oceanography  
Tributyltin (TBT) is a very toxic compound that was used as antifouling paints

biocide during more than four decades. Due to the environmental toxicity the International Maritime Organization banned TBT-based antifouling paints in September 2008. Thereafter, TBT environmental concentrations as well as imposex levels (the most widely used TBT biomarker) have been declining in several coastal areas worldwide. However, Brazil and Uruguay are the only signatory countries of the antifouling systems convention and recent studies have shown that TBT contamination is still an important issue along South American coastal areas. Thus, the incidence of imposex and butyltin compounds (BTs) was appraised in three selected areas from South America. Muricid gastropods and surface sediments were sampled in sites under the influence of harbors and marinas from Venezuelan Caribbean Sea (Venezuela), Fortaleza (Brazil) and Lima (Peru). Imposex parameters (% imposex, RPLI and VDSI) and BTs levels were determined and the results were spatially evaluated considering potential TBT sources (harbors and/or marinas). In addition, a time-trend for imposex and BTs levels were evaluated for Fortaleza and Lima. Despite the general pattern of reduction, areas under the influence of marinas always presented high TBT and imposex levels. VDSI and RPLI ranged from 3.8 to 4.6 and 49.4 to 54.6 in marinas of Venezuela, whilst values were much lower for other coastal areas (0.2 to 1.9 and 0.1 to 5.6, respectively). In Fortaleza (Brazil), VDSI and RPLI values were  $\leq 0.92$  and  $\leq 10.9$  in sites under the influence of harbors and up to 4.2 and 97.0 in areas under influence of leisure boats (marina and yacht club). At Peru, much higher levels of imposex (RPLI =  $8.4 - 28.4$  / VDSI =  $3.3 - 3.5$ ) and TBT in tissues ( $24-61$  to  $111-145$  ng Sn g<sup>-1</sup>) were detected in two sampling sites after the establishment of a marina in 2010. Thus, although the international restrictions on TBT use are apparently reducing the inputs from harbors, these three independent studies from Venezuela, Brazil and Peru clearly pointed out that marinas are becoming an important source of fresh TBT pollution. Based on that, a similar pattern might be expected for other South American coastal areas.

#### TH176

##### **Decreased BT levels and changes in Imposex development in *Hexaplex trunculus* (Gastropoda, Muricidae) from the Northern Adriatic Sea (Italy)**

**F. Cacciatore**, ISPRA-Institute for Environmental Protection and Research / Mitigation and Prevention of Impacts; C. Antonini, M. Formalewicz, C. Gion, ISPRA - Institute for Environmental Protection and Research; S. Noventa; D. Berto, R. Boscolo Brusà, ISPRA - Institute for Environmental Protection and Research; M. Marin, University of Padova / Department of Biology  
Imposex (superimposition of male sexual characteristics on females of gonocohoristic gastropods) is an endocrine disruption effect used to indirectly assess the presence of tributyltin (TBT), a once popular biocide in antifouling paints, which has been worldwide banned since 2008. The aim of this study was to measure concentrations of butyltin compounds (BT), i.e. TBT with its di- and mono- substituted metabolites (DBT and MBT), and to observe imposex levels in gastropods from a site with relatively low boat density traffic, focusing on seasonal variations and size differences naturally occurring in molluscs. From July 2013 to June 2014, individuals of *Hexaplex trunculus* with shell lengths of three sizes (30-60; 60-70; 70-80 mm) were monthly collected 7 NM offshore in the Gulf of Venice (Northern Adriatic Sea, Italy). Very low concentrations of BTs were detected (range  $\Sigma$ BT:  $9 - 16$  ng Sn g<sup>-1</sup> dw), with DBT almost always higher than TBT levels, except in spring samples where maximum BT concentrations were also detected, probably related to decreases in meat yield linked to spawning season. No relationship was found between shell size and BT body burden. Out of the 392 *H. trunculus* assessed, 46% were male and 54% were female. Imposex Incidence (%), expressed as the percentage of affected females, was 78%. Vas Deferens Sequence Index (VDSI) of 0-4, Relative Penis Size Index (RPSI) of 0-1.8% and Female Penis Length (FPL) of 0-3mm were found. Seasonal and size differences were found only for RPSI and male penis lengths. The development of imposex exhibited a different course respect to that observed in *H. trunculus* from the same area before TBT ban, when BT concentrations and imposex levels were much higher. Previous studies documented first the development of the incipient penis, followed by the development of vas deferens. In this study, the onset of imposex occurred with the appearance of the vas deferens halfway between the right ocular tentacle and vagina. The observed change was supposed to be a consequence of the decreased BT concentrations in the environment.

#### TH177

##### **Analysis of organotin compounds in antifouling paint particles**

**M. Lagerström**, Institute of Applied Environmental Science ITM; J. Strand; E. Ytreberg, Chalmers University of Technology / Department of Shipping and Marine Technology; B. Eklund, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES  
Antifouling paints containing organotin compounds (OTC), primarily tributyltin (TBT), have been banned from use on boats shorter than 25m in the EU since 1989 due to their harmful effects, amongst others as an endocrine disruptor, on non-target organisms. However, even though the use of organotin paints has ceased, recreational boats remain sources of OTC to the environment as many have historical coatings of organotin paint on their hulls. Paint particles containing OTC end up on the ground in the boatyards during boat maintenance or in harbour sediments where the OTC are released from the shed particles. As the persistence of biocides from antifouling paints have been shown to be higher in sediments when they are introduced as paint particles, they can act as long-term sources. It is

therefore important for risk assessment purposes to be able to accurately quantify the amount of TBT and other OTC in sediments. The extraction efficiency of OTC from paint flakes using an extraction and derivatization method for sediments employed at a lab accredited for butyltin compounds was tested against a modification of the method containing an additional extraction step involving a solvent mixture with a composition similar to that of paint thinner. The comparison shows that not only did the yield of OTC increase with the modified method but an increased number of organotin species could also be detected. The results from this comparison indicate that quantification of TBT and other OTC in sediments using existing methods may lead to an underestimation, if paint flakes are present in the sample.

#### TH178

##### **Environmental quality standards for Bisphenol A**

**R.J. Brown**, wca consulting; D. Leverett, WCA-Environment Ltd; G. Merrington, Environment Agency  
Bisphenol A (BPA) is used in the manufacture of plastics, has been widely detected in the aquatic environment and there are concerns about its effects on the environment and on human health. As such BPA is considered to be a candidate for eventual 'priority substance' status under article 16 of the Water Framework Directive (WFD, 2000/60/EC) which will require that EU-wide Environmental Quality Standards (EQSs) are derived. This poster will outline the process used to derive EQS values and uses it to derive PNEC values for BPA based on available acute and chronic aquatic ecotoxicity data. While existing risk assessments (e.g. E.C. 2008) are used as the basis for the PNEC evaluation, there is a considerable amount of new data available for this substance (post 2008) which were not included in previous assessments. This data has been assessed for reliability and relevance and combined with the existing data to derive aquatic PNEC values using both deterministic and probabilistic approaches. A long-term freshwater aquatic PNEC of 16.5 µg/L was obtained for BPA using a probabilistic assessment. This is the preferred approach for deriving a PNEC for this substance given the large database of available environmental data for BPA. The application of safety factors for deriving EQS values will be discussed taking into consideration available mesocosm data and the potential concerns for low dose effects of BPA. Human health biota and drinking water PNECs of 304 µg/kg and 17.5 µg/L respectively were also derived using EFSA's recently revised Tolerable Daily Intake (TDI) of BPA of 5 µg/kg/bw/day. The available monitoring data suggests that BPA in the environment would not readily exceed the proposed EQS. Ref: E.C., (2008): Update of the risk assessment of 4,4'-Isopropylidenediphenol (Bisphenol-A), Environment Addendum.

#### TH179

##### **Developing a hierarchical testing strategy for micropollutants in drinking water regarding potential endocrine disrupting effects**

**J. Kuckelkorn**, RWTH Aachen University / Institute for Environmental Research; R. Redelstein, RWTH Aachen University / Albrecht von Haller Institute for Plant Sciences; T. Heide, J. Kunze, S. Maletz, RWTH Aachen University / Institute for Environmental Research; T. Grummt, Federal Environment Agency / Toxicology of Drinking Water and Swimming Pool Water; A. Eckhardt, Federal Environment Agency / Drinking Water and Swimming Pool Water Toxicology; H. Hollert, RWTH Aachen University / Institute for Environmental Research; T. Seiler, RWTH Aachen University / Ecosystem Analysis  
The joint project "Tox-Box – Risk assessment of anthropogenic micropollutants to assure the drinking water supply" (BMBF FKZ 02WRS12821) aims for a harmonized, hierarchic test strategy to assess the toxicity of micropollutants that may occur in drinking water by means of the health-related indicator value (HRIV concept). This concept offers five HRIV threshold values ( $\leq 0.01$  µg L<sup>-1</sup> to  $\leq 3$  µg L<sup>-1</sup>) depending on availability and completeness of toxicological data regarding genotoxicity, neurotoxicity and germ cell damages. As one part of the Tox-Box module "endocrine effects" the Institute for Environmental Research at RWTH Aachen University analyzed and established endocrine activity as an important, additional toxicological mode of action within this concept using a set of bioassays. The *in vitro* ERα/ AR CALUX® assay detected receptor-mediated endocrine activity in the human osteosarcoma cell line U2-OS (± S9 fraction for metabolic activation). A second *in vitro* assay, the H295R steroidogenesis assay, identified alterations in the steroidogenesis of hormones 17β-estradiol and testosterone with a competitive ELISA and effects on the expression of different steroidogenic genes (CYP11A, 3βHSD2, CYP17A and CYP19A) using quantitative real-time PCR in the human adrenocortical carcinoma cell line H295R. The *in vivo* reproduction toxicity assay with the mud snail *Potamopyrgus antipodarum* provided data on endocrine disruption at an individual as well as population level. Results indicate that the combustion product benzo[a]pyrene (BaP), the pharmaceuticals diclofenac and sulfamethoxazol, the flame retardant tris (1-chloro-2-propyl) phosphate, the herbicides atrazine, 3,4-dichloroaniline (3,4-DCA) and 2,4-dichlorophenol (2,4-DCP), the fungicide tributyltin oxide (TBTO), the radio contrast agent diatrizoic acid and the industrial chemical perfluorooctanoic acid have no affinity to the estrogen and androgen receptor without metabolic activation, even when applied at their water solubility limit. Using an S9-mix BaP, 3,4-DCA, 2,4-DCP and 3,3-dichlorobenzidine (3,3-DCB) showed effects, the latter also without S9-mix. Atrazine, 2,4-DCP and TBTO caused effects on hormone production in the H295R assay, which can be correlated

with changes in the expression of steroidogenic genes. BaP caused an effect in the reproduction test with *P. antipodarum* with a LOEC of 40 ng L<sup>-1</sup>.

#### TH180

##### **Predicted effect concentrations and distribution of progestins in European aquatic environment**

**V. Kumar**, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters; **A.C. Johnson**, CEH Wallingford / Wallingford; **R. Grabic**, University of South Bohemia in CB / Faculty of Fisheries and Protection of Waters, South Bohemian Research Center of Aquaculture and Biodiversity of Hydrocenoses; **H.K. Kroupová**, University of South Bohemia in Ceske Budejovice / Faculty of Fisheries and Protection of Waters

Studies show that at minute level of steroidal hormones in natural waters can be harmful to aquatic organisms. In recent years, concern has been raised about the natural progesterone and its synthetic derivatives (progestins). There are evidences that some progestins can contribute to endocrine disruption in fish and other aquatic organisms. For example, at the lowest tested concentration 0.8 ng/L, levonorgestrel (LNG) reduced egg production of female fathead minnows by about 95%.

However, there is almost no detail study on the occurrence and distribution of these chemicals in aquatic environment. In the absence of occurrence data, it is highly desirable to have a range of effect values for progestins in aquatic environment. To address these issues we selected specific candidates based on their reported concentrations in literature data and their likely potential threat to aquatic wildlife. For our study, reported effluent values of LNG and norethisterone were used to predict their concentrations in European rivers. As a starting point we used national dilution factor values for European countries. LNG does not appear to pose a widespread threat to European fish reproduction, however in some locations of Romania, Spain and UK known effect concentration (0.8 ng/L) would be reached for brief periods. Furthermore, predicted bioconcentration factor values can be used to derive effect concentration of progestins in water. We found that some progestins would have a tendency to accumulate in fish, when present in the surrounding water at low ng/L levels. Derived effect concentration values suggested that ethynodiol diacetate and desogestrel were most likely to be bioconcentrated in fish up to human plasma therapeutic levels since an environmental concentration of only 2 to 3 ng/L in the surrounding waters was required. Overall, distribution assumed from the effluent concentrations could make a significant contribution to improve our knowledge on the presence of these chemicals in European aquatic environment.

VK was supported by the project The Creation of PD Positions at the University of South Bohemia and the Support of Intersectional Mobility by Expert Stays at the Foreign Leading R&D Institutions (CZ.1.07/2.3.00/30.0006).

#### TH181

##### **Quantification of plasticizers by UHPLC-MS/MS and application to a drinking water treatment plant**

**G. Bolívar-Subirats**; **M. Cortina-Puig**, Escola Universitària Salesiana de Sarrià; **M. Boleda**, **Agbar**; **S. Lacorte**, IDAEA-CSIC / Environmental Chemistry

Plasticizers are a group of substances added to plastics to modify their physical properties as flexibility or durability. Phthalates have been used for a long period of time in the industry. Plasticizers are considered as emerging environmental pollutants as a result of their extensive use and their endocrine disrupting properties. These plasticizers are present in plastic pipes, used in industry and also in drinking water treatment plants, and they are capable to migrate from the plastic to water due to temperature and the period of time the water is in contact with this material. The aim of this work was to develop a method for the analysis of 22 plasticizers (dimethyl phthalate, diethyl phthalate, benzyl butyl phthalate, dibutyl phthalate, bis(2-ethylhexyl)adipate, bis(2-ethylhexyl) phthalate, benzophenone, bisphenol A, 7 butylphenol isomers, 4-tert-amylphenol, 4-cumylphenol, 4-heptylphenol, 4-octylphenol, 4-nonylphenol, 4-dodecylphenol) by ultra high performance liquid chromatography-tandem mass spectrometry (UHPLC-MS/MS) operating in multiple reaction monitoring mode. Solid phase extraction with Oasis HLB cartridges was used to analyse water in the different stages from a drinking water treatment plant: river water, sand filtration, ozonization, carbon active, ultra filtration, reverse osmosis and treated water. Phthalates, BPA, nonylphenol and octylphenol were detected in different stages. Bisphenol A was the only target compound completely eliminated throughout the treatment plant. Other contaminants were present at low µg/L level. Tolerable daily intake (TDI) defined by the European Food Safety Authority, was calculated to estimate the consumption of the target compounds. It was calculated taking into account the highest concentration detected of each compound in the distribution waters analysed within this study, and 2 L water ingestion per day for a 60 kg person. In all cases, values are well below the TDI. **Acknowledgement** - The authors thank the Ministry of Education, Science and Innovation in Spain (INNFACTO, IPT-2011-0709-060000).

##### **On the importance of metabolism for identifying potential endocrine disruptors in industrial chemicals - evaluation and development of in silico tools**

**A. Rybacka**, Chemistry Department; **C. Ruden**, Stockholm University / Department of Environmental Science and Analytical Chemistry ACES; **I. Tetko**, Helmholtz Zentrum München, German Research Center for Environmental Health; **P.L. Andersson**, Umea University / Chemistry Department

Several endocrine disrupting chemicals (EDCs) are known to undergo fast metabolic transformation and some pathways are induced by metabolites rather than by the parent compounds. Experimental data on the metabolic fate of chemicals are scarce, but metabolite simulators, which can provide insights and guidance, are available. By predicting possible metabolites, these *in silico* systems can provide inputs for quantitative structure-activity relationship (QSAR) models to assess the effects associated with endocrine activity of untested metabolites. The aim of this study is to improve the identification of EDCs by developing and evaluating *in silico* tools that predict three types of endocrine alteration: estrogen (E), androgen (A), and transthyretin (T) binding. In particular, the study focuses on evaluating the use of a metabolism simulator to reduce the number of false negatives predicted by EAT models. A large database was collected to reach a wide model applicability and the developed models were applied on the European inventories of high and low production volume industrial chemicals (H&LPVCs) aiming at identifying potential EDCs. Balanced accuracies of the EAT models ranged from 77-87%, 62-77%, and 65-89% for E-, A-, and T-binding respectively. Of a large set of industrial chemicals to which the models were applied in order to generate predictions, 9% were E- and/or A-binders and 1% were T-binders. The numbers of E- and T-binders increased 2- and 3-fold, respectively, when a metabolism simulator was applied. An evaluation of *in vivo* data showed that the metabolism simulator predicted metabolites with 50% accuracy and could correctly identify compounds interfering with thyroxine levels *in vivo*. Combined use of the EAT models and the metabolism simulator resulted in identification of 50% of industrial compounds present on standard lists of potential endocrine disruptors such as the TEDX[1] and EU priority lists. The data and models used in this study will be publicly available on-line at <http://ochem.eu>. <br clear="all" /> [1]<http://endocrinedisruption.org/endocrine-disruption/tedx-list-of-potential-endocrine-disruptors>

#### TH183

##### **Exposure Assessment of Phthalate Esters for Chinese Population Based on Exposure Scenario and Biomonitoring Estimation Methods**

**Y. Cao**; **J. Liu**, **X. Hao**, Peking University

Phthalate esters are widely used as plasticizers and consequently ubiquitous in environmental media and human bodies. The possible adverse health effects and various exposure pathways made phthalate esters a general concern. On the basis of extensive monitoring data available around China, this study evaluated exposures to Di(2-ethylhexyl) phthalate (DEHP), di-n-butyl phthalate (DBP) and diisobutyl phthalate (DiBP) using exposure scenario method and biomonitoring estimation method at the same time. The median exposure levels from scenario estimation and biomonitoring estimation were 4.36, 2.78 and 1.03 µg/kg bw/day and 3.38, 3.21 and 3.32 µg/kg bw/day for DEHP, DBP and DiBP, respectively, showing acceptable levels of exposure, compared with the reference dose (RfD) and tolerable daily intake (TDI) values released by the EPA or the EU. Meanwhile, Food is the main exposure source for both DEHP and DBP while indoor air and dust have a significant contribution to the estimated daily intake of DiBP. Regional assessment in several developed areas with large plastic productions obtained higher exposure levels, which should be paid more attention in the context of rapid development of the plastics industry. **Keywords**: phthalate esters; exposure assessment; exposure scenario method; biomonitoring estimation method

#### TH184

##### **Assessing the relationship between perfluoroalkyl substances, thyroid hormones and binding proteins in pregnant women; a longitudinal mixed effects approach**

**V. Berg**, Laboratory Medicine; **T. Haugdahl Nøst**, NILU Norwegian Institute for Air Research; **S. Hansen**, University of Tromsø / Department of Community Medicine; **A. Elverland**, University hospital of Northern Norway / Laboratory Medicine; **A. Veyhe**, University of Tromsø / Department of Community Medicine; **R. Jorde**, University of Tromsø; **J. Odland**, UiT The Arctic University of Norway; **T.M. Sandanger**, UiT The Arctic University of Norway / department of community medicine

The mechanisms involved in thyroid homeostasis are complex, and perfluoroalkyl substances (PFASs) have been indicated to interfere at all levels. Disruption of the maternal thyroid homeostasis during early pregnancy is of particular concern, where subclinical changes in maternal thyroid hormones (THs) may affect embryonic and foetal development. The present study investigated associations between THs, thyroid binding proteins (TH-BPs) and PFAS concentrations in pregnant women from Northern Norway. Women participating in The Northern Norway Mother-and-Child Contaminant Cohort Study (MISA) donated a blood sample at three visits related to their pregnancy and postpartum period (during the second trimester, 3 days and 6 weeks after delivery) in the period 2007-2009. Participants were assigned to quartiles according to PFAS concentrations during the second trimester and mixed effects linear models were used to investigate potential associations between PFASs and repeated measurements of THs, TH-BPs, thyroxine binding capacity and thyroid peroxidase antibodies (anti-TPO). Women within the highest perfluorooctane sulfonate (PFOS) quartile had higher mean concentrations

of thyroid stimulating hormone (TSH) compared to the first quartile at all sampling points. Women within the highest quartiles of perfluorodecanoate (PFDA) had lower mean concentrations of triiodothyronine (T3) and women within the highest quartile of perfluoroundecanoate (PFUnDA) had lower mean concentrations of free triiodothyronine (FT3). Further, the difference in concentrations and the changes between three time points were the same for the PFAS quartiles. Thyroxin binding capacity was associated with all the THs and TH-BPs, and was selected as a holistic adjustment for individual changes in TH homeostasis during pregnancy. Finally, adjusting for maternal iodine status did not influence the model predictions. Findings in the present study suggest modifications of TH homeostasis by PFASs in a background exposed maternal population. The variation in levels of THs between PFAS quartiles were within normal reference ranges and may not be of clinical significance in the pregnant woman. However, subtle individual changes in maternal THs may have significant consequences for foetal health.

#### TH185

##### **Exposure to persistent organic pollutants (POPs) in pregnant women and newborn infants and associated endocrine disruption effects**

S. Kim, Seoul National University / Department of Environmental Health; J. Park, SOON CHUN HYANG UNIVERSITY / College of Natural Sciences; S. Kim, Seoul National University; H. Moon, Hanyang University / Marine Sciences and Convergent Technology; K. Choi, Seoul National University / School of Public Health

Persistent organic pollutants such as polychlorinated biphenyls, polybrominated diphenyl ethers, and organochlorine pesticides are of global concern because of their widespread contamination and adverse health effects. Due to the susceptibility of fetus to prenatal exposure to POPs, pregnant women are important group which deserves such investigation. In the present study, associations between POPs exposure and thyroid hormones or adipokine levels among the pregnant women and matching children were investigated. We observed that significant disruption of thyroid hormones at the current levels of exposure to POPs in pregnant women, and that prenatal exposure to several POPs were associated with decrease of T3/T4 levels and increase of TSH in cord serum and neonatal bloodspot both. In addition, we found the significant influence of POPs exposure to disturbance of adiponectin and leptin production in breast milk. Considering the importance of thyroid hormones and adipokines during gestation and early life stages and the effects of interaction between thyroid hormone and adipokines concentration on obesity or weight loss, health implication of low level POPs exposure among newborns and pregnant women deserves further follow up investigations.

#### TH186

##### **Internal dosimetry metrics for risk assessment of endocrine disruptors - the case of bisphenol A**

D.A. Sarigiannis, S. Karakitsios, E. Handakas, A. Gotti, Aristotle University of Thessaloniki / Chemical Engineering

A major outcome of INTEGRA project (CEFIC LRI) is a computational platform that integrates multimedia environmental, (external) exposure and toxicokinetic modelling within a dynamic framework in time. Use of toxicokinetic modelling transforms exposure/risk assessment of environmental chemicals since it allows risk characterization to be based on internal dosimetry metrics. In this way high throughput system data such as the ones generated by Tox21 *in vitro* testing can be used, towards the nowadays need of “exposure based risk assessment”. This opens the way towards a higher level of assessment that incorporates refined exposure (tissue dosimetry) and toxicity testing (Biological Pathway Altering Dose – BPAD). The applicability of INTEGRA was tested on bisphenol-A. Several exposure scenarios were investigated, (a) incorporating data from external exposure assessment based on food residues and food consumption patterns, (b) from exposure reconstruction of real life EU-wide human biomonitoring data using exposure reconstruction algorithms. Reconstructed exposure was then run in forward mode in the PBBK model, so as to estimate the Biologically Effective Dose (BED) in the target tissue. In order to associate the risk of the several exposure scenarios based on BED derived by the PBBK model, two different exposure metrics were used: - The Tolerable Daily Intake (TDI) of 50 µg/kg bw/d proposed by the European Food Safety Authority, was translated into internal exposure, found to correspond to a concentration of 0.16 µg/L of free plasma BPA. - In vitro, the ToxCast assays provided six ER agonist or binding AC50 values for BPA, ranging from 0.6 to 1.7 µM. To calculate a conservative Biological Pathway Altering Dose (BPAD), the lowest ToxCast AC50 was selected (0.64 µM for Attagene Factorial cis ERE assay). This estimated concentration (145 µg/l), is 3 orders of magnitude higher than the equivalent derived from the EFSA TDI (0.16 µg/l). The assessment indicated that taking into account age dependent bioavailability differences of BPA, specific exposure scenarios (i.e. bottle fed neonates and premature infants hosted in intensive care units) result in BED close to the EFSA TDI legislative threshold. Use of the ToxCast AC50 BPAD as an internal exposure risk characterization metric, resulted in increased margins of safety compared to conventional exposure/risk characterization.

#### TH187

##### **Classification of the Ecological Quality Status of the Portuguese coast concerning TBT pollution, based on the levels of imposex in two gastropod species.**

F. Laranjeiro, Biology Department CESAM; P. Sanchez Marin, University of Aveiro & CESAM / INRSETE; I.B. de Carvalho Benta Santos Oliveira, University of Aveiro & CESAM / Biology department; S. Galante-Oliveira, C. Barroso, University of Aveiro / Biology Department CESAM

The Water Framework Directive (WFD) and the Marine Strategy Framework Directive (MSDF) were developed in the European Union in order to protect aquatic ecosystems. One of the emphasized concerns in these directives is the pollution by contaminants like tributyltin (TBT), a biocide largely used in antifouling paints in the past and considered the causative agent of imposex in gastropods, as well as other known deleterious effects. In order to integrate TBT pollution assessment within these legislative frameworks, Ecological Quality Ratios (EQR) were developed for imposex assessment in two different gastropod species, the dogwhelk *Nucella lapillus* and the netted whelk *Nassarius reticulatus*. Those EQRs were then applied to an imposex monitoring campaign performed in 2014 along the Portuguese coast, in order to classify the Ecological Quality Status. According to our proposal, the levels of imposex observed in *Nucella lapillus* indicate that all assessed sites present a Good Ecological Quality status. The same conclusion is obtained when using the proposed EQR by the WFD-United Kingdom Technical Advisory Group (WFD-UKTAG) in this species. On the other hand, imposex levels exhibited by the netted whelk showed that some stations present a Moderate to Poor/Bad Ecological Quality Status, namely the ones located in fishing ports and dockyards. As TBT is listed as a priority substance in the WFD Annex X, the monitoring of this compound should be performed regularly. Our combined approach involving these two species is an effective and low cost tool to assess the environmental quality status regarding TBT pollution under the WFD. The 2014 survey showed that despite the 2008 IMO global ban on TBT application as a biocide in AF systems on ships, as well as other previous restrictions on its use, there is still evidence of high levels of this pollutant at some sites along the Portuguese coast.

#### TH188

##### **The planar-YES bioassay: a new approach to measure the effects of oxidation procedures on surface water samples**

A. Schönbörn, A.A. Grimmer, ZHAW

The planar-YES ([2],[3]), a variation of the yeast estrogen screen (YES) [1]) was used to assess the efficacy of three different oxidation procedures for the removal of microcontaminants from potential drinking waters. The procedures were: a) ozonation, b) chlorination, and c) advanced oxidation (AOP) using hydrogen peroxide and ozone. The raw water samples were divided into two lines, one of them left native and the other being spiked with 9 selected microcontaminants found in Swiss surface waters. The two samples were then subjected to each of the 3 oxidation procedures, with samples being taken before and after oxidation. This results in 12 different measurements per sample. All samples were then extracted using solid phase extraction. We showed that all 3 oxidation processes are able to remove a significant part of estrogenic activity from the water, but traces still remain active. We also showed that chlorination can lead to a small but significant increase of estrogenic activity in treated surface water after the procedure. The reasons of this are currently still unknown. Our work also lead to a significant improvement of the planar-YES method, namely in the application technique of the yeast culture to the HPTLC plates. The planar-YES is an interesting tool for the assessment of estrogenic activity in aqueous samples of various kinds (e.g., surface waters, recycled water, water from fish culture, water stored in plastic packages etc) and should receive more attention in the scientific community. It offers a way to connect effect-directed analysis to chemical analysis with much less effort than with other strategies. Masses as low as 0.5 pg 17-beta-estradiol equivalents per spot can be detected. The method has the potential to avoid solid phase extraction by allowing the application of native water samples directly on plate. We are convinced that the limit of detection has still not yet been reached. The next steps of our research will focus on the direct detection of estrogenic substances in TLC-bands by using TOF-MS. **References:** [1] E.J. Routledge, J.P. Sumpter, Environ. Toxicol. ## **Carbonaceous materials for contaminants remediation (P)**

#### TH189

##### **Interactions between unconventional biochars and organic contaminants**

M. Kah, University of Vienna / Department of Environmental Geosciences; G. Sigmund, H. Sun, University of Vienna; T. Hofmann, University of Vienna / Department of Environmental Geosciences

Biochars can exhibit great sorption potential towards heavy metals and organic contaminants, and have therefore been proposed to sequester contaminants for remediation purposes. Most biochars studied so far were derived from plant residues and little knowledge is available for biochars derived from waste materials and that are characterized by high mineral contents (e.g., sewage sludge, manure). Using wastes as feedstock to produce biochars would support the development of attractive combined strategies for waste management and remediation. High mineral contents are expected to strongly affect sorption behaviour, especially that of compounds interacting through specific mechanisms of sorption (e.g., polar,

ionizable compounds). In this study, single point sorption coefficients for a series of model sorbates were measured onto a series of biochars produced at 200°C, 350°C and 500°C. Feedstock materials consisted of wood shavings (yielding biochars with < 1% ash), pig manure (biochars with 30-60% ash) and sewage sludge (biochars with 50-70% ash). A commercial biochar derived from grain husks was also included (40 % ash) and sorption to a commercial activated carbon was used as a benchmark. For a selected subset of materials, detailed experiments were also carried out to investigate the effects of particle size fractions and acid demineralization. Harsh extraction with organic solvent indicated acceptable contents of inherent polycyclic aromatic hydrocarbons (within the guidelines values proposed by the International Biochar Initiative). Sorption affinity strongly depended on the biochar – sorbate combination and covered an extremely wide range of values ( $1 < \text{Log } K_d < 6.5 \text{ L/kg}$ ). All materials were extensively characterized (e.g., elemental composition, surface area and porosity) and multivariate analyses were applied to identify the factors driving the great discrepancies in sorption observed. Overall, we demonstrate that (i) biochars derived from animal wastes have potential for remediation applications, and that (ii) describing the interactions between unconventional biochars (e.g., animal waste) and sorbates (e.g., ionizable compounds) requires the consideration of parameters that are typically not accounted for (e.g., ash content, pH).

#### TH190

##### **Sorption of halogenated phenols and pharmaceuticals to biochar: Affecting factors and mechanisms**

S. Oh, University of Ulsan / Department of Civil and Environmental Engineering; Y. Seo, University of Ulsan

The feasibility of using biochar as a sorbent to remove nine halogenated phenols (2,4-dichlorophenol, 2,4-dibromophenol, 2,4-difluorophenol, 2-chlorophenol, 4-chlorophenol, 2-bromophenol, 4-bromophenol, 2-fluorophenol, and 4-fluorophenol) and two pharmaceuticals (triclosan and ibuprofen) from water was examined through a series of batch experiments. Types of biochar, synthesized using various biomasses including fallen leaves, rice straw, corn stalk, used coffee grounds, and biosolids, were evaluated. Compared to granular activated carbon (GAC), most of the biochar samples did not effectively remove halogenated phenols or pharmaceuticals from water. The increase in pH and deprotonation of phenols in biochar systems may be responsible for its ineffectiveness at this task. When pH was maintained at 4 or 7, the sorption capacity of biochar was markedly increased. Considering maximum sorption capacity and properties of sorbents and sorbates, it appears that the sorption capacity of biochar for halogenated phenols is related to the surface area and carbon content of the biochar and the hydrophobicity of halogenated phenols. In the cases of triclosan and ibuprofen, the sorptive capacities of GAC, graphite, and biochars were also significantly affected by pH, according to the point of zero charge (PZC) of sorbents and deprotonation of the pharmaceuticals. Pyrolysis temperature did not affect the sorption capacity of halogenated phenols or pharmaceuticals. Based on the experimental observations, some biochars are good candidates for removal of halogenated phenols, triclosan, and ibuprofen from water and soil.

#### TH191

##### **Insights into Sorption Mechanisms of Hydrophobic Organic Compounds on Activated Carbon by means of Scanning-Transmission-X-ray-Microscopy (STXM)**

T. Gocht, University of Tuebingen / Institute for Experimental and Clinical Pharmacology and Toxicology; M. Obst, University of Tuebingen / Center for Applied Geosciences

Polycyclic aromatic hydrocarbons (PAHs) are among the most important pollutants since high concentrations of this compound group occur at many contaminated sites (e.g. former gaswork sites, harbor sediments, etc.). Carbonaceous materials such as soot, charcoal, unburned coal and kerogen exhibit very strong (sorption) affinities for PAHs. Consequently, activated carbon has been applied at contaminated sites such as harbor sediments to sequester pollutants. However, the efficiency of such amendment strategies may be affected by sorption of other compounds such as dissolved natural organic matter (competitive sorption). Today it still remains an open question how ageing of carbonaceous materials, subsequent to mixing into soils and sediments, change the sorption properties of the geosorbents. In our study we used scanning transmission x-ray microscopy (STXM) to visualize the distribution of phenanthrene as a model compound for PAHs among different treatments of activated carbon. Prior to the phenanthrene sorption batch experiments, the sorbent was treated with oil or humic acid, respectively. Phenanthrene as well as the organic co-sorbents (oil, humic acid) was mapped on activated carbon by means of their NEXAFS (near edge X-ray absorption fine structure) fingerprints. The results revealed reduced sorption of phenanthrene in case of the humic acid treatment and the visualization and quantification with STXM showed that humic acid accumulates mainly at the outer surface of the activated carbon particles, whereas phenanthrene migrates into the intraparticle pore space. This suggests reduced diffusion of phenanthrene into the particles due to the surface coverage with humic acid. In contrast, similar distributions of phenanthrene and oil were observed in case of the oil-treated activated carbon, indicating that the oil may either compete with phenanthrene for the same sorption sites, or provide an additional sorption domain within the particles for hydrophobic organic contaminants (i.e., partitioning of phenanthrene into the oil within the

intraparticle pore space).

#### TH192

##### **Photocatalytic degradation of methylene blue dye in aqueous solutions by pyrolytic tyre char/TiO<sub>2</sub> composites**

V. Makrigianni, Uniy of Patras / Department of Environmental and Natural resources Management; A. Giannakas, C. Daikopoulos, Y. Deligiannakis, University of Patras; I. Konstantinou, Department of Environmental and Natural resources Management

In this work the preparation of TiO<sub>2</sub>/tyre rubber pyrolytic char (PC) composite photocatalysts via a simple sol-gel method was studied. The photocatalytic performance of the PC/TiO<sub>2</sub> catalysts has been assessed for the photooxidation of methylene blue aqueous solutions in order to evaluate the possible synergistic effect of PC and optimize the (wt. %) char/TiO<sub>2</sub> ratio. Catalysts with different weight ratio of Char (C) to Ti (T) were prepared as follows: CT0.2/2, CT0.5/2, CT0.7/2, CT1.0/2 and TiO<sub>2</sub>-blank. Anatase TiO<sub>2</sub> crystal phase was obtained for all the composite catalysts and traces of brookite crystal phase were formed in TiO<sub>2</sub>blank (@ 4%) and CT 1.0/2 (@ 10%) as determined by XRD analysis. The average crystal size of anatase TiO<sub>2</sub> ( $d_{\text{anatase}}$ ) ranged from 13 to 20 nm. The surface areas ( $S_{\text{BET}}$ ) for composites catalysts are proportional to the amount of char in the catalysts and ranged from 43.96 to 127.2 m<sup>2</sup>g<sup>-1</sup> for the PC/TiO<sub>2</sub> catalysts CT 0.2/2 - CT 1.0/2, respectively. Electron Paramagnetic Resonance (EPR) spectra were recorded at 77K with a Bruker ER200D spectrometer, equipped with an Agilent 5310A frequency counter operating at the X band. The irradiation of methylene blue/catalysts suspensions was carried out using a Suntest XLS + apparatus (Atlas, Germany) simulating natural sunlight irradiation. The composite catalysts PC/TiO<sub>2</sub> exhibited an improved photocatalytic degradation of MB in comparison with pure-TiO<sub>2</sub>. The photocatalytic degradation rates of MB by the prepared composite photocatalysts, followed apparent first-order kinetics. The CT 0.2/2 catalyst showed the highest photocatalytic efficiency and nearly complete degradation was achieved within 300 min irradiation. The EPR analysis showed that incorporation of TiO<sub>2</sub> onto PC results in faster photokinetics of <sup>•</sup>OH generation in solution due to the enhanced h<sup>+</sup> generation in the TiO<sub>2</sub> crystal while the pyrolytic carbon matrix acts as a sink for the photoinduced electrons which migrate from the TiO<sub>2</sub> conductivity band. This results in an increased h<sup>+</sup> lifetime due to diminished hole-electron recombination. **Acknowledgement** - This work is financially supported by the "SYNERGASIA" Program 11SYN\_5\_682 (O.P. Competitiveness & Entrepreneurship (EPAN II), ROP Macedonia- Thrace, ROP Crete/n and Aegean Islands, ROP Thessaly- Mainland Greece- Epirus, ROP Attica).

#### TH193

##### **Effect of grain size and heavy metals on As immobilization by calcium carbonate**

M. SIMON TORRES, I. GARCIA FERNANDEZ, University of Almería / Agronomy Department; V. Gonzalez, Laboratoire interdisciplinaire des environnements continentaux LIEC CNRS UMR; A. Romero Freire, F.M. Peinado, University of Granada / edafologia y química agrícola

The effect of grain size and the interaction of heavy metals on As sorption by marble waste with different particle sizes was investigated. Acidic solutions containing only arsenic and a mixture of arsenic, lead, zinc and cadmium, were put in contact with the marble waste. The amount of metal(loid)s that were immobilized was calculated using the difference between the concentration in the acidic solution and in the liquid phase of the suspensions. The objective was to assess the effect of grain size and the interaction of heavy metals on As sorption by marble particles in an effort to add value to marble waste through a better understanding of its properties. Arsenic was sorbed onto marble grains both specifically (forming inner-sphere complexes) and non-specifically (exchangeable and forming outer-sphere complexes). The sorbed amount was approximately 420 µg As m<sup>-2</sup>, with the inner-sphere complexes being the major fraction (61±7% of the total As sorbed). The As that precipitated did not exceed 20% of the total As in the solution, and therefore, marble particles should not be considered an effective amendment to immobilize As. However, when the contamination involved arsenic and other heavy metals, particularly Pb, then, in addition to sorbed As, Pb-Ca arsenate crystals formed on the surface of the marble grains. The formation of these crystals increased with a greater SS of the marble grains to the extent that in the suspensions with greater SS (0.608 m<sup>2</sup> g<sup>-1</sup>), the As concentration in the liquid phase decreased by 95% relative to the total dissolved As, whereas the amount of Pb was reduced by almost 100%. Arsenic that precipitated as Pb-Ca arsenates was not extracted with (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> or with NH<sub>4</sub>H<sub>2</sub>PO<sub>4</sub>, which suggests that they are relatively stable compounds and, therefore, effective in immobilizing As and Pb in contaminated water and soil.

#### TH194

##### **Biochar as an alternative to activated carbon for polluted soil remediation.**

B. Pjurova, VSB - Technical university of Ostrava; T. Natal da Luz, University of Coimbra / Department of Life Sciences; J.M. Sousa, Faculty of Engineering of University of Porto / Chemical Engineering; X. Domene, CREA-Universitat Autònoma Barcelona / Unit of Ecology

Biochar is a carbonaceous solid product resulting from biomass pyrolysis, which is due to its large surface area, cation exchange capacity, hydrophobicity and liming capacity considered as promising potential tool for reducing the bioavailability of

both organic and inorganic contaminants. This is why a role of biochar in polluted soil remediation has been proposed, either due to a decreased bioavailability of pollutants that reduce the possible accumulation and toxicity to organisms, but also due to the potential enhancement of organic pollutant's biodegradation by stimulation of microorganism's activity. Since biochar production is expected to increase in the next future, the aim of this paper was to assess the usefulness of biochar for remediation of contaminated soils as a suitable alternative to activated carbon. Springtails (*Folsomia candida*) were used as bioindicators considering the reproduction improvements as an indication of remediation efficiency. Three polluted soils from Czech Republic, Spain and Portugal with contrasting pollutant composition (mostly Cr, Zn, Pb, Cu and BTEX) were amended with two biochars (produced by slow pyrolysis and gasification, both obtained from the same pine wood chip allotment) and an activated charcoal (AC) at application rates of 0 (control), 5 and 10% (w/w). The models derived for *F. candida* reproduction suggest that, in the only soil where remediation was significant (Czech Rep.), both biochar and activated charcoal were able to reduce heavy metal bioavailability, at least partly due to their liming capacity in this acid soil. In two other soils, no evidence of remediation capacity for biochar and also activated charcoal was observed. Furthermore, some of the biochars were shown to cause toxic effects themselves when applied at high rates. The contrasting results observed in different polluted soils point out the need for further investigation, but also the need for an accurate selection of the most suitable biochars for each remediation scenario.

#### TH195

##### **Bridging the gaps between analytical and effects-based characterization of biochars as remediation agents**

X. Domene, CREA-Universitat Autònoma Barcelona / Unit of Ecology; A. Bastos, University of Aveiro / Department of Biology and CESAM  
Biochar is the carbonaceous product of biomass pyrolysis, intended for application to soils as a cross-cutting strategy to improve soil functions and sequester carbon. A more recent role in remediation of contaminated or polluted soils and sediments has been also suggested. Despite the present scientific and societal interest in combining soil/environmental benefits with pollutant mitigation, biochar as a potential emerging soil contaminant or a source of contaminants has been only recently addressed. The feedstock and pyrolysis technology define the physical-chemical characteristics of the resulting biochar, leading to a wide variety of materials. The same factors determine the pollutant burden in biochar, as well as the bioavailability of such compounds over time. Large-scale application of poorly characterized biochars may lead to detrimental impacts overcoming the expected environmental benefits, something that might be prevented by the eco(toxico)logical risk assessment of biochars at relevant application rates. Current biochar standardization/certification efforts in the EU and the US are vital for quality assessment and control. While much progress has already been achieved in defining biochar physicochemical quality criteria, effect-based approaches bridging analytical characterization and observed effects on exposed biota are generally omitted. Bioassays are effect-based tools able to assess biochar's bioavailable fractions (rather than total contaminant load) and possible synergistic or antagonistic interactions between concurrent contaminants. Further, they also enable evaluating positive effects of biochar by itself or their efficiency as remediation agent once applied to soil. A selected set of state-of-the-art methodologies developed for ecotoxicological assessment of chemicals is presented and their possible contribution discussed in the context of predictive (i.e. characterization) as well as of retrospective (i.e. eco(toxico)logical effects) risk assessment of biochars. Only by combining physical-chemical and biological tools, one can effectively understand, predict, manage or mitigate the potential environmental risks associated to large scale biochar applications.

#### TH196

##### **Adsorption of endocrine disruptors using industrial wastes based materials**

J. Souza, P. Freitas, Universidade Federal de Minas Gerais / Chemistry; M. Rosmaninho, Universidade Federal de Minas Gerais / Química; L.D. Almeida, T.R. Santos, Universidade Federal de Minas Gerais / Chemistry  
The endocrine disruptors represent a new type of waste that has aroused interest due to be harmful to the environment even in the low concentrations that they are usually found. Among the different techniques proposed to remove such residues, the adsorption using carbonaceous materials has been showed as a promising method. In this work the adsorption of ethinylestradiol, hormone present in contraceptive pills, was studied. The adsorbent materials used were produced from wastes of electrical and electronic equipment (WEEE) and glycerine, a by-product of the biodiesel production. To produce the adsorbent milled integrated circuit waste was mixed with glycerol (proportion 2:1) and small amount of sulphuric acid as catalyst. The mixture was heated under nitrogen flow (50 mL min<sup>-1</sup>) at 600 °C to promote the carbonization of the glycerol catalysed by the metals present in the WEEE. An activated sample was also prepared using CO<sub>2</sub> flow (50 mL min<sup>-1</sup>) at 450 °C for 4 hours. The samples were characterized by TGA, Raman, DRIFTS, SEM, surface area, ICP-AES, XRD, XRF and UVS. The adsorption tests were performed using 10 mg of adsorbent and 10 mL of a solution 20 vol.% of acetonitrile in water containing 10 mg L<sup>-1</sup> of ethinylestradiol. After 24h the amount of ethinylestradiol removal was determined by UV-Vis Spectroscopy ( $\lambda=280$  nm). The TGA, DRX, ICP-AES and XRF analyses shown that the WEEE is composed mainly by polymers (25 wt.%) and ceramic materials (i.e. Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub>; 32 wt.%), as

well as Cu, Ca, Br, Fe, Sn, Zn, Ni, Ag, Au, I, Ti, Cr, Sb, Pb, Sr and Nb. After thermal treatment with glycerol were observed the formation of carbonaceous phases, both organized as amorphous, and the presence of oxidized groups (i.e. hydroxyls, carbonyl, etc.). The adsorbents, original and activated, shown surface areas of 60-65 m<sup>2</sup> g<sup>-1</sup> and average porous sizes of about 11 Å. The adsorption tests demonstrated that both original and activated materials were able to reduce the concentration of ethinylestradiol in solution of 6-8 %, bigger to the CO<sub>2</sub>-activated adsorbent. Although apparently low, the amount of ethinylestradiol typically present in urban waste water are below the adsorption capacity of the produced adsorbent. In addition, the materials were also produced from other low cost industrial wastes (WEEE and glycerol). Therefore, the produced materials are promising to use as adsorbent to emergent contaminants.

#### TH197

##### **Levels of dioxins, furans and PCBs in biochar and biotar from agricultural waste**

J. Diaz-Ferrero, Institut Químic de Sarrià / Environmental Laboratory; V. Arrufat, R. Martí, University Ramon Llull IQS / Environmental Laboratory; O. Pou, University Ramon Llull IQS / Department of Industrial Engineering  
Last years, biochars, carbonaceous materials produced during the pyrolysis of biomass, have been studied as materials that can contribute positively to the mitigation of climate change, in waste management strategies, in the energy production field and for soil improvement. However, some concern has arisen about the possibility of by-product formation, such as polyaromatic hydrocarbons or polychlorinated dibenzo-p-dioxins, polychlorinated dibenzofurans and polychlorinated biphenyls (PCBs). Dioxins, furans and PCBs were the target of this work. Samples studied were the biomass used for the pyrolysis process (hazelnut shells) and the solid (biochar) and liquid (biotar) produced. Two different conditions were tested for the pyrolysis: (A) temperature was increased at 9°C/min from room temperature to 110°C (held 50 min), increased at 12°C/min to 230°C (held 10 min) and increased at 22°C/min to 450°C (held 10 min); (B) temperature was increased at 9°C/min from room temperature to 110°C (held 50 min), increased at 8°C/min to 450°C (held 30 min). After this temperature programs, the solid remaining (biochar) was collected, as well as the liquid condensed (refrigerated by cold water). The main steps of the analytical methodology were the following: (1) addition of <sup>13</sup>C<sub>12</sub>-labelled internal standards, (2) extraction, (3) clean-up in a multilayer silica column (4) fractionation in SPE carbon tubes to obtain PCDD/F fraction and a PCB fraction, (5) separation of DL-PCB from the bulk of PCBs by HPLC equipped with a pyrenyl column (6) concentration, (7) instrumental determination by HRGC-HRMS and (8) quantitation. Biotar was liquid-liquid extracted with hexane and biochar with toluene in a Soxhlet equipment. Although the levels of dioxins and furans in the samples analyzed were very low (below 0.30 pg TEQ/g), some differences were observed: biotar samples showed the highest concentrations. In addition, some changes in the profiles of the congeners were detected. A proportional enrichment of 2,3,7,8-TCDF in biochar and biotar samples could indicate the formation of this compound in the process. For PCBs, similar trends were observed for total concentrations, with highest levels in biotar samples. Profiles of PCBs were quite similar among all the samples.

#### TH198

##### **MERCURY CAPTURE ON REGENERABLE SORBENTS DURING COMBUSTION (CONVENTIONAL & OXY)**

D. Ballester, Universidad San Jorge; C. GÓMEZ-GIMÉNEZ, R. JUAN, B. RUBIO, CSIC - Spanish National Research Council; M. Pino, San Jorge University / Facultad ciencias de la salud; M. IZQUIERDO, CSIC - Spanish National Research Council  
Mercury is a highly toxic trace metal of environmental concern because of its properties like volatility, persistence, bioaccumulation in the environment and its neurological health impacts. This metal is readily methylated by microorganisms, bioaccumulates in biota and consistently biomagnifies through the food chain. Mercury can be emitted in a natural way like volcanoes and anthropogenic way. Due to anthropogenic mercury emissions, the concentrations of mercury are three times higher than in pre-industrial days. Among all mercury anthropogenic sources, power plants burning fossil fuels are estimated to account for about 25% of the global anthropogenic mercury emissions. Technologies like activated carbon injection (ACI) are used for mercury capture, but large amount of toxic wastes are obtained in this abatement process. The objectives of this work are the development of a waste free process for mercury capture. This process is based on a novel gold nanoparticles/carbon regenerable sorbent and consists of gold nanoparticles supported onto structured carbon monoliths. Mercury capture capacity and efficiency have been evaluated. Sorbents are characterized by inductively coupled plasma (ICP), scanning electron microscope (SEM), field emission scanning electron microscope (SEM-FE), X-ray photoelectron spectroscopy (XPS). Sorbents were tested in a bench scale experimental installation working at high space velocities 25000 h<sup>-1</sup> and at Hg inlet concentration of 100 µg Hg/m<sup>3</sup>. Mechanism of mercury retention is the amalgamating and dealumating property of mercury for gold. Two different retention temperatures (50 °C and 120°C) and two different atmospheres (N<sub>2</sub> and CO<sub>2</sub>) have been evaluated. The regenerability has been tested performing cycles of capture-regeneration at 250 °C. High mercury capture efficiencies were obtained for the sorbents tested, with low gold content, indicating that this novel regenerable sorbent is a promising material for mercury capture in a

waste free process. Moreover, the mercury capture capacity doesn't depend on temperature allowing the use of these sorbents at different positions on the power plants.

#### TH199

##### **The influence of pH on adsorption of arsenic from aqueous solution by amino-functionalized multi-walled carbon nanotubes**

J. Trickovic, S. Maletic, M. Kragulj, M. Watson, University of Novi Sad Faculty of Sciences; M. Prica, University of Novi Sad Faculty of Technical Sciences / Department of Graphic Engineering and Design; S. Roncevic, University of Novi Sad Faculty of Sciences; B. Dalmacija, University of Novi Sad, Faculty of Sciences / Department of Chemistry, Biochemistry and Environmental Protection

The main objective of this work was to investigate the adsorption mechanism of As(III) from water on amino-functionalized multi-walled carbon nanotubes (AF-MWCNT). Since both As(III) chemistry and the surface chemistry of AF-MWCNT depend upon the pH, adsorption was investigated at three different pH values (3, 6 and 11). Adsorption experiments were performed using a conventional batch technique at room temperature. The background solution was 0.01 M CaCl<sub>2</sub> in deionised water. The amount of AF-MWCNT in each experiment corresponded to a sample/solution ratio that resulted in 20-80% uptake of As(III). The initial concentration of As(III) was in the range 0.6 - 3 mg L<sup>-1</sup>. The pH was adjusted by HNO<sub>3</sub> or NaOH solution. The samples were agitated on a horizontal shaker for 30 h. The time to reach adsorption equilibrium was obtained from a kinetic study performed over a period of 72 h. After reaching equilibrium, the adsorbent was settled for 24 h and a sample of clear supernatant taken, filtered using a 0.22 µm filter, acidified with cHNO<sub>3</sub> and analyzed by atomic absorption spectrophotometry (Perkin Elmer AAnalyst 700, USA). Kinetics data followed pseudo-second order model ( $R^2 > 0.979$ ), indicating that the adsorption mechanism of As(III) on AF-FMWCNT can mainly be attributed to chemical interactions between the surface functional groups and As(III) species. Using the Weber-Morris model it was determined that intra-particle diffusion also contributes to the adsorption of As. However, in all cases, the nonzero intercepts of the Weber-Morris plots were a clear indication that although intra-particle diffusion is slow, it is not the slowest of the rate processes that determine the overall order. The interaction between As(III) species and the surface of the AF-FMWCNT remains the most significant rate process. Adsorption capacity, calculated using the Langmuir adsorption model, decreased as pH increased from 3 to 11 from about 40 mg g<sup>-1</sup> to about 11 mg g<sup>-1</sup>, indicating that adsorption is highly influenced by the pH value of the solution. **Acknowledgement:** This work has been produced with the financial assistance of the Ministry of Education, Science and Technological Development of the Republic of Serbia (Project III43005). The project is co-financed by kind support of Provincial Secretariat for Science and Technological Development of the Autonomous Province of Vojvodina (Grant no. 114-451-1158).

#### TH200

##### **Use of nanoparticles in environmental remediation - the effects of carbon nanoparticles in pharmaceuticals toxicity**

R. Oliveira, University of Brasilia / Department of Genetics and Morphology; D.S. Moura, Universidade de Brasilia / Genética e Morfologia; J.T. Souza, University of Brasilia / Departamento de Genética e Morfologia Instituto de Biologia; N.O. Farias, R.C. Oliveira, Universidade de Brasilia Gtox / Departamento de Genética e Morfologia Instituto de Biologia; C.K. Grisolia, University of Brasilia / Department Genetics and Morphology

Aquatic and terrestrial ecosystems are under constant pressure due to human activities that among other impacts can cause pollution and degradation of water and soil resources. The remediation of the toxic effects of pollutants is essential in order to maintain the quality of the environment and hence the welfare and human health. This project brings an innovative approach that integrates the two important fields of science - nanotechnology & environment - aiming the remediation of terrestrial and aquatic ecosystems impacted by emerging pollutants, drugs, especially psychiatric medications and antimicrobial. Nanotechnology is a current, high-interest promotes technological knowledge associated with particles having at least one dimension on the gauge scale (< 100 nm) science. Nanotechnology may also contribute to the sustainable development of the human society through new tools for environmental remediation and even new methods of treatment of complex mixtures. Carbon nanoparticles and metal-oxide nanoparticles are the objects of study in this project, because these have been proposed for decontamination of environmental samples contaminated with organic and inorganic compounds. Detection of several drugs of human and veterinary use in natural ecosystems has called attention of government authorities and the scientific community. These have shown the active ingredients of drugs as the main contaminants present, classifying them as emerging pollutants. The scientific community has shown to the governmental authorities the needed to seek new methods to estimate both, the risk of pharmaceuticals to the environment, and to control the adverse effects impacted areas. The main objective of this project is to investigate the applicability of carbon nanoparticles in the remediation of the toxic effects of drugs detected in water resources and in solid waste (often used in agricultural soil fertilization). In the first stage of the project aimed to achieve a bold set of tools for diagnosis and analysis of the environmental effects of water contamination by antimicrobial and psychiatric drugs using zebrafish as biosensor. Thus, scientific bases that can generate protocols and processes for the remediation

of soils and waters contaminated by drugs will be produced.

#### TH201

##### **Activated Carbon in Sediment Remediation - Adverse Effects vs. Remediation Potential**

S. Abel, University of Eastern Finland / Department of Biology; I. Nybom, Department of Biology; S.E. Hale, Norwegian Geotechnical Institute / Environmental Engineering; G. Cornelissen, NGI; J. Akkanen, University of Eastern Finland / Department of Biology

The *in-situ* treatment of contaminated aquatic sediments with activated carbon (AC) has been shown to be highly efficient in reducing mobility and bioavailability of persistent organic pollutants. However, it has also been found that the sorbent material itself might have toxic effects on benthic organisms. This study deals with the question if there are suitable ways to reduce the adverse effects of the sorbent material on the benthic community while still maintaining its high contaminant binding potential. Three different variants of AC (different manufacturers and raw materials), two different particle size ranges, as well as different application methods (mixing with sediment and thin layer capping) were assessed. Additionally it was tested, if the addition of clay to the sorbent material has a significant impact on its performance. *Lumbriculus variegatus* was chosen as a model organism. Both natural, field-contaminated (PCB's) sediment and clean artificial sediments were used as substrate. The organism's vital functions were monitored to assess the toxicity of the sorbent materials. The sorbent's effect on PCB tissue concentration was observed to evaluate the remediation potential. The results showed that AC mixed into the sediment could lower PCB bioaccumulation in the tissue of *L. variegatus* significantly already at doses of 0.1%, while AC doses of 1.0% led to a reduction of more than 90%. Correspondingly a significant impact on the test organism's vital function was observed in the presence of AC particles. Feeding rates dropped drastically in the 0.1% dose and with 1.0% of AC in the sediment a near-cease of any feeding activity was observed. This was accompanied by reduced growth (0.1% AC) and even a loss of biomass (1.0% AC) over an exposure time of 28 days. The three tested AC variants did not differ significantly in their performance. Similar adverse effects were observed when AC was applied as a thin layer cap. The presence of the sorbent generally led to a significant loss in biomass over 28 days. Unlike when mixed into the sediment, the AC dose (cap thickness) had no significant impact on adverse effects. The severity of the reduction in growth was only affected by the AC particle size.

#### TH202

##### **Effects of compost as an organic carbon amendment to reduce DDT and dieldrin bioavailability to native earthworms**

M. Anderson, Civil and Environmental Engineering; A. Torrents, University of Maryland / Civil and Environmental Eng; L. McConnell, USDA Agricultural Research Service / Environmental Management and Biporoduct Utilization Laboratory; N.A. Andrade, University of Maryland / Civil and Environmental Engineering; R. Chaney, C.J. Hapeman, USDA-ARS

Historic soil contamination as a result of agricultural application is a common occurrence throughout the world. Agrichemicals such as dichlorodiphenyltrichloroethane (DDT) and dieldrin are hydrophobic organic contaminants and persist in the environment long after application, particularly in soil. The present study investigated bioavailability reduction as a remediation strategy for an aged contaminated orchard site. Following a laboratory scale pot study, two types of local compost were chosen as organic carbon amendments for a small plot study in an orchard which historically received DDT and dieldrin applications. In the initial pot study, five organic amendments were evaluated, and the two chosen poultry manure composts showed the greatest decrease in earthworm bioavailability over a 45 day incubation period. In the current research, portions, or plots, in the contaminated site had silt fence barriers installed to restrict earthworm movement but allow normal hydrological activity. The silt fence was used to create a total of seven plots divided into 4 sub-plots each. Each sub-plot was randomly assigned one of four treatments: each of the two composts, which were tilled into the soil, one non-amended tilled area, and an undisturbed section. Contaminant concentrations in the soil and native earthworms were determined at three time points over one year to evaluate any changes in bioavailability over time.

#### TH203

##### **Environmental remediation using carbon nanostructured compounds: the toxic effects of caffeine**

N.O. de Farias, Departamento de Genética e Morfologia; R. Oliveira, University of Brasilia / Department of Genetics and Morphology; C.K. Grisolia, University of Brasilia / Department Genetics and Morphology

The occurrence of caffeine (Caf) in natural waters has drawn attention of regulators and researchers worldwide. Caffeine is present in a wide variety of aquatic environments, including wastewater treatment plant effluents, surface waters, groundwater and even remote mountain lakes. For these reasons, there is an immediate concern to understand how this compound may cause affect natural ecosystems acting as a toxic agent. Nanotechnology emerged as an alternative to remediate the toxic effects of organic and inorganic contaminants. In this context, the nanostructured carbons compounds (NCC) are highlighted as an alternative for remediation due to its ability adsorb pollutants. The aim of this study was to

evaluate the application of NCC in the remediation of caffeine toxic effects. To do so, in a first step, the acute toxic effects of Caf and CNC were evaluated separately, using zebrafish embryos as bioindicators. The OECD Protocol no. 236 "Fish Embryos Toxicity (FET) test" was used to assess the lethal and embryotoxic effects of seven treatments of Caf, 0, 30.1, 45.3, 68.2, 102.6, 154.5, 232.5 mg/L. The test was extended to 7 days of duration. For NCCs, a test was performed with two different particles, CNC 824 and CNC alfa, in a single exposure dose of 100 mg/L. In a second step, the embryos were exposed to caffeine solutions after filtration with both NCCs. All tests were incubated in a climatic chamber at  $26 \pm 2$  °C, 12 h of light. The results of this study demonstrate that extend fish embryo toxicity test is a powerful tool for assessing the toxicity of Caf. Despite the low toxicity of Caf ( $7d-LC50 = 106.0 \pm 35.5$  mg/L) several abnormalities in development were observed in concentrations from 10 mg/L. Thus, the effects on embryonic development indicate that in chronic exposure with lower Caf could affect embryo-larval stages of fish in natural ecosystems. The NCCs did not cause significant lethal effects on zebrafish embryos. Also, do not interfere with embryonic development, causing only a slight inhibition in hatching after 48 hours of exposure. In summary, the results obtained reinforce the potential of these new NCCs to develop innovative nanotechnology products for water remediation. Future studies might focus on predictive models of toxicity that can be applied in the development of protocols and processes of remediation of contaminated waters.

## TH204

### Soil nematode communities as indicators of medium-term ecological impacts of biochar addition to agricultural land

X. Domene, CREA-Universitat Autònoma Barcelona / Unit of Ecology; S. Mattana, CREA; S. Sánchez-Moreno, Instituto Nacional de Investigación y Tecnología Agraria y Alimentaria (INIA) / Unidad de Productos Fitosanitarios. Agricultural soil mesocosms were amended in 2011 with a pine chip gasification biochar (0, 12 and 30 t/ha), fertilized with pig slurry, and cropped to barley. After two years, soil nematode communities as indicator of ecosystem impacts were assessed. Soil samples were taken in May and October 2013 and nematodes extracted in Baermann funnel. Nematodes were counted and identified to genus or family under microscope, in order to assess taxa richness and to calculate the Maturity Index. Furthermore, each individual was assigned to a feeding guild (bacterial feeders, fungal feeders, plant parasites/herbivores, omnivores, and predators) for the calculation of soil food web indices (Structure Index, Channel Index, Basal Index, and Enrichment Index). The bacteria-to-fungi ratio was also determined in each sample by qPCR. Of the 31 taxa identified, only the basal bacterivore *Cervidellus* was significantly affected by biochar addition, with higher abundance in the 30 t/ha rate in both samplings. The bacterivore *Acrobeloides* and the fungivore/herbivore *Tylenchidae* presented a significant interaction sampling x biochar rate. Globally, the bacterivore relative abundance increased with biochar addition, while the abundance of herbivores and predators decreased with biochar rate. Ecological indices were not affected by biochar addition and only differed between samplings (taxa richness, the Enrichment Index, and the Structure Index). While in May the soil food web condition was similar in all the biochar treatments, in October a more degraded condition was observed at the higher biochar rate. In summary, some negative effects of the addition of this pine gasification biochar were observed at the highest application rate, clearly over the usual agricultural amendment rates but in the range of rates used for soil restoration or remediation purposes. The results from this study point out the need to include ecotoxicological tests in biochar quality assessment guidelines, as well as field studies, to ensure the environmental benefits of this technology and the accurate selection of biochars to be used in soil.

## TH205

### An integrated approach to assess the aquatic effects of biogenic and petrogenic activated carbon used for remediation purposes

A. Macken, NIVA / Ecotoxicology and Risk Assessment; M. Schaanning, Norwegian Institute for Water Research; A. Lillicrap, NIVA / Ecotoxicology and Risk Assessment. Activated carbon (AC) has long been associated with the capacity to effectively remove organic substances from aquatic and sediment matrices, however, its use in remediation purposes has drawn some concern due to possible impacts on benthic communities. Within the inner Oslofjord, the use of AC has been well documented for removing dioxins or dioxin like compounds from contaminated sites. However, benthic surveys performed on areas treated with activated carbon have revealed that the abundance of organisms inhabiting these areas has been reduced significantly in the subsequent years following treatment. The reason for the reduction in the benthic communities is currently unknown and therefore an integrated approach to assess the effects of 2 different forms of activated carbon (biogenic and petrogenic) on benthic organisms has been performed. A battery of 3 different benthic organisms (*Tisbe battagliai*, *Arenicola marina*, *Chironomus riparius*) with different feeding and life-cycle processes has been used encompassing sediment surface feeders, sediment ingestors and sediment re-workers. The results of the tests indicated that although activated carbon is not acutely toxic at concentrations up to 1000 mg/L, there may be physical effects of the substance on benthic dwelling organisms at environmentally relevant concentrations of activated carbon. The results of the battery of assays are discussed in the context of field based AC capping in Norway. In addition an assessment of "at risk" functional groups *in situ*

is discussed to assess the benefits versus impacts of AC as an amendment technique for contaminated sediments (Hydrophobic organic contaminants (HOCs)).

## TH206

### How humic substances affect the sorption behavior of carbon-based nanomaterials

T. Hüffer, University of Vienna / Department of Environmental Geosciences; S. Schroth, University of Duisburg-Essen / Instrumental Analytical Chemistry; T. Schmidt, University of Duisburg-Essen. Research on carbon-based nanomaterials (CNM) has been increasing over the past decade due to their unique physico-chemical properties. The question of their fate and impact on the environment has become a major concern due to an expected rise in their production in the future. Even though there is consensus that CNM will eventually reach the environment, their environmental behavior and impact on the fate of other pollutants remains controversial. Nevertheless, research in the field of environmental behavior of CNM has been increasing drastically. However, the data are comparable only to some extent as for all CNM (i) different probe sorbates were investigated and (ii) various humic substances (HS) were chosen (i.e., kinds or concentrations). Regarding sorption of hydrophobic organic compounds (HOC) and HS by CNM there are two major mechanisms that have been considered: (a) sorption of either HOC or HS as single solutes by CNM and/or (b) competitive sorption of HOC influenced by HS. For the latter, two main mechanisms have been proposed how HS may affect HOC sorption. Either, HS directly competes with HOC for sorption sites on CNM surface, which seems especially relevant as commonly low sorbate and high NOM concentrations were combined; or sorption of HOC is reduced by large HS molecules that block the entrances of CNM pores that may otherwise be available for HOC sorption [1,2]. Furthermore, sorption of HOC to HS bound to CNM has to be taken into account despite the fact that this is typically much weaker than on CNM itself. To systematically study this process, three alkane pairs were selected as molecular probe sorbates. The influence of HS on sorption affinity, sorption linearity, and the dominant sorption mode (i.e., *ad-* or *absorption*) by multi-walled carbon nanotubes (MWCNT) was investigated. The addition of HS led to a continuous decrease in sorption affinity and an increase in sorption linearity with increasing HS addition. Furthermore, the comparison of distribution coefficients of *n*- and cycloalkanes showed that the dominant sorption mode remains to be *adsorption* regardless of the presence of HS on MWCNT surface [3]. [1] Wang et al. (2009) *Environ.Sci.Technol.*, 43, 6214-6219. [2] Zhang et al. (2010) *Water Research*, 44, 2067-2067. [3] Hüffer et al. (2015) *Chemosphere* 2015, 109, 1169-1175.

### Activated Kraft Lignin as an alternative sorbent for sediment remediation with thin-layer capping: Comparison with activated carbon derived from charcoal and coconut

A. Gustafsson, J. Gunnarsson, Stockholm University / Department of Ecology Environment and Plant Sciences DEEP; G. Cornelissen, NCI; E. Sjöholm, Innventia. Thin-layer capping with activated carbon (AC) may be a promising remediation technique of contaminated sediments *in situ*, especially in larger areas, where dredging is not an option. Most carbonaceous sorbents tested for capping are produced either from charcoal or from coconut shells in Asian or African countries and need to be transported long distances for remediation in western countries. There is a need for more locally produced C sorbents. In this study a new type of C sorbent, derived from locally produced Kraft Lignin (KL), a by-product from paper pulp production, was compared for its sorption capacity to ACs from charcoal and coconut. Soft wood Kraft Lignin (KL) was isolated from black liquor through a recent biorefinery process called LignoBoost, developed to convert lignin into novel biomaterials. The KL was then activated through KOH treatment and pyrolysis. The activated KL (AC-KL) was then compared to AC derived from charcoal (AC-ch) and AC derived from coconut (AC-co) using sorption and bioavailability assays. *Sorption assays*: were done by mixing contaminated sediment (5 g dw) collected from Bergen harbor with 0.5 g dw of activated carbon (AC-Ch, AC-Co or AC-KL) in 40 ml filtered seawater in Erlen flasks. Passive samplers (POM-55) were added, and the flasks were incubated for 72 days on a rotating shaker. After incubation the POMs were extracted and analyzed for PCBs and PAHs and compared to controls without AC amendment. *Bioavailability assays*: were done on the same treatments using synthetic digestive fluid extractions. Freundlich isotherms and digestive fluid extraction efficiencies (DFEE) were determined for a selection of PAHs (i.e. pyrene) and PCBs. Sorption capacity was comparable for the three AC types with the highest sorption obtained for AC-coconut, followed by AC-charcoal, and then the carbonized lignin (CKL). E.g. dissolved concentrations of pyrene were reduced by 92 % with AC-ch, 90 % with AC-co and 76% with AC-KL relative to controls without AC. These results were confirmed by the bioavailability assays, DFEEs, though often close to the detection levels, showed the same trend as the sorption values. Our results show that activated Kraft lignin could offer a local carbon source alternative to other ACs, should it be produced in sufficient large amount and at a competitive price.

## TH208

### Reduction of copper bioavailability with biochar and compost in vineyard soils with elevated copper concentrations

G. Soja, AIT Austrian Institute of Technology GmbH / Health and Environment; G.

Pardeller, V. Fristak, AIT Austrian Institute of Technology GmbH; L. Deinhofer, S. Johnen, University for Natural Resources and Life Sciences Vienna; F. Rosner, LFZ Klosterneuburg; A. Dellantonio, AGES; G. Dersch, Austrian Agency for Health and Food Safety; F. Zehetner, University for Natural Resources and Life Sciences Vienna

Copper concentrations in agricultural soils may be elevated because of applications of pesticides with Cu-compounds as active ingredients. Especially in vineyards CuSO<sub>4</sub> has been an important tool to fight downy mildew since the 19<sup>th</sup> century. Especially in wine-growing regions with a long history of viticulture fungicide applications caused Cu-concentrations in top soil, occasionally exceeding 200 mg.kg<sup>-1</sup>. Although such concentrations do not affect grapevines and do not lead to elevated Cu concentrations in grapes or wine, they are ecotoxicologically relevant in the top soil where they may affect soil microbiology and annual vegetation for soil cover. Cu cannot be removed from vineyard soils but its bioavailability may be reduced by appropriate soil additives. Biochar with its high sorption capacity for cations is a potential soil amendment that may reduce the ecotoxicologically most relevant copper species, Cu<sup>2+</sup>. This study had the objectives to test the hypothesis that biochar as soil additive decreases the bioavailability of Cu and to screen different biochars and mixing ratios for their effectiveness. The sorption behavior of Cu to biochar were at first investigated by sorption experiments according to the batch equilibrium method in single-component systems. Equilibrium sorption parameters were calculated from adsorption models and the parameters of adsorption isotherms were calculated by nonlinear regression analysis. A supplementary pot experiment was installed with soils from two vineyards with EDTA-Cu-concentrations of 110 and 250 mg.kg<sup>-1</sup> in the top soil. These soils were mixed with wood-based biochar at application rates equivalent to 1 to 8 kg.m<sup>-2</sup>. Different treatments varied in the proportion of compost addition, in application rates and in post-treatment carboxylation of the biochar. The pots were planted with vines and soil cover vegetation. Seepage water was recovered by suction plates at the bases of the pots. Cu translocation to the plants was studied by leaf analyses. Soil samples were analysed for differences in bioavailability of Cu. First results showed reduced growth and vitality in the vines and soil cover vegetation in the soil with higher Cu concentrations although the Cu concentrations in the leaves were not similarly elevated. Reduction of bioavailability of Cu was observed in the soil on the basis of Cu-speciation analysis in soil extracts, showing a distinct increase in the ratio of organically bound Cu to Cu<sup>2+</sup>.

## Sustainability of Mediterranean olive oil production (P)

### TH209

#### Biochemical responses of *Olea europaea* L. cv. chemlali exposed to air and soil pollution near the industrial complex in Sfax, Tunisia

Z. MOHAMED, Faculty of pharmacy LIMOGES; C. Ben Ahmed, Faculty of Sciences Sfax; N. Elloumi, Faculty of Sciences of Sfax; M. Krayem; D. Delmail, Institute of Sciences Chimiques de Rennes; B. Ben Rouina, Faculty of Sciences of Sfax; P. LABROUSSE, Université de Limoges; F. Ben Abdallah, Faculty of Sciences of Sfax

This study aims to evaluate the impact of complex air and soil pollutions on *Olea europaea* L. cv. chemlali, one of the most important commercially valuable crops in Tunisia. These field experiments were performed in the vicinity of the industrial complex in the South of Sfax, Tunisia for the polluted olive trees and in unpolluted areas for control ones. Several biomarkers were studied belonging mainly to the antioxidant system like enzymes or antioxidant compounds. Main results indicate that air and soil pollutions induced an oxidative stress as demonstrated by an increase in the rate of hydrogen-peroxide (H<sub>2</sub>O<sub>2</sub>) production, electrolyte leakage, and lipid peroxidation in all plant parts. This stress affects chlorophyll and carotenoid contents of leaves. Additionally, the activities of enzymes involved in reactive-oxygen-species (ROS) detoxification were affected. Air and soil pollutions induce an increase in the activities of ascorbate peroxidase (APX), superoxide dismutase (SOD) and catalase (CAT). Moreover, in polluted olive trees, the content of antioxidant molecules like polyphenols, flavonoids and anthocyanins increases strongly. This is consistent with the role of these potent antioxidants in scavenging ROS such as H<sub>2</sub>O<sub>2</sub>. This study evidences the deleterious effects of industrial activity on antioxidative defense system of *Olea europaea* L. cv. Chemlali. Keywords: Air pollution, olive tree, reactive oxygen species, antioxidative defense system

### TH210

#### Development of Soil Water Repellency and Secondary Acidification Effect after OMW Application in an Olive Orchard in Palestine

n.t. tamimi, Universität Koblenz-Landau / natur und umweltwissenschaften; D. Diehl, Universität Koblenz-Landau / Institute for Environmental Sciences; G.E. Schaumann, University of Koblenz-Landau / Institute of Environmental Sciences Olive mill wastewater (OMW) is generated seasonally in large amounts. Often it is applied to soils. There, OMW may exert negative effects due to its high salinity, oil and grease content, acidity and high content of phenolic compounds. The objective of this study was to investigate the persistence and degree of soil water repellency (SWR) during different seasons of OMW application in soil. Our aim was to elucidate to which extent this phenomenon could be associated with soil acidity and concentration of phenolic substances under different climatic conditions. A field study was conducted in Palestine. In order to mimic different climatic conditions,

OMW application (14 L m<sup>-2</sup>) was conducted either in winter, spring or summer on two replicate plots. An addition application was conducted on two irrigated plots in summer. For each of the treatments, we implemented two control plots with tap water application. Soil samples were collected after 2 days, 3 weeks, 6 weeks, 3 months, 6 months, 9 months, 12 months, and 18 months in 5 depth down to 35 cm. Aqueous soil extracts were analyzed for pH, EC, cations, anions and total soluble phenolic compounds. SWR was measured in the field using water drop penetration time (WDPT). Generally, OMW was found to induce SWR. SWR (re-)developed gradually during the hot summer season following OMW application. The extent of hydrophobization was strongest in the summer dry, intermediate in the spring and weakest in the moist summer application plots. Acidification effects were strongest for summer dry, intermediate for summer wet and lower for spring applications, whereas no effect were observed following winter OMW application. In summer dry application phenolic concentration was higher compared to spring application. During the first rain season following OMW applications, water repellency in all treatments disappeared and the phenolic concentration decreased to the control level. The results indicate that during warm and moist conditions, i.e., when microbial activity is high, phenolic compounds are degraded and the induced repellency decreased fast. In contrast, under hot and dry conditions, phenolic compounds probably polymerized thus increasing acidification. Induced SWR was resistant and even increased. Under cold and moist conditions, high initial WDPT rather indicates limitation in hydraulic conductivity than repellency. Phenolic compounds probably were washed out. **Keywords: Olive mill wastewater, Water drop penetration time, Acidity, Total phenol**

#### Does a soil recover within twelve months after olive mill wastewater land spreading? - Searching for a sustainable solution.

M.P. Kurtz, Environmental and Soil Chemistry / Environmental Science; Y. Laor, Agricultural Research Organization / Neve Yair Research Center RamatYishay Israel; A. Dag, Agricultural Research Organization / Gilat Research Center Israel; G.E. Schaumann, University of Koblenz-Landau / Institute of Environmental Sciences

Controlled land spreading of olive mill wastewater (OMW) is a widely used agricultural disposal option for this problematic waste. As a product with high nutrient and organic matter content it can serve as fertilizer. However, potential soil hydrophobicity, accumulation of salts and toxic residuals like phenols creates problematic side effects. Soil recovery between successive OMW spreading is an important criterion in terms of environmental protection and sustainability when searching for a cheap and effective OMW solution. A field study served to investigate rate dependent soil recovery after two years of consecutive spreading of OMW in rates of 50, 100, 150 m<sup>3</sup> ha<sup>-1</sup> year<sup>-1</sup> and, additionally, 100 m<sup>3</sup> ha<sup>-1</sup> year<sup>-1</sup> followed by tillage. The field is an irrigated olive orchard in the semi-arid south of Israel and its soil type is a light brown sandy loam. pH, EC, soluble ions, soluble phenolic compounds (SPC), organic matter, water drop penetration time, soil biological activity (bait-lamina test) were determined depth dependently (0-3 cm, 3-10 cm, 10-20 cm, 20-40 cm, 40-60 cm) twelve months after the last OMW application. Changes of soil properties following OMW application are still detectable 12 months after application of small rates of OMW down to 50 m<sup>3</sup> ha<sup>-1</sup> year<sup>-1</sup>. While the upper soil layer showed significant changes compared to the control, which strongly depend on the rate, no effects were found in soil layers below 20 cm. EC and chloride as well as phosphate, organic matter and SPC contents increased significantly in all treatments. Nitrate contents decreased after OMW application. The biological activity in the soils was significantly higher in the treated plots independent of the application rate. Tillage after OMW application decreased the SPC contents compared to the same application rate without tillage and showed also higher biological activity in deeper soil layers. Moreover it had the lowest water drop penetration. Successive and consecutive land spreading of OMW is not supported by the findings of this study. Incomplete degradation of phenolic substances and soil salinization are alarming outcomes with respect to long-term OMW spreading. Tillage after OMW spreading is a promising option towards a sustainable solution.

##### Consideration of inter-population variability to improve ecological relevance of biomarkers

O. Dedourge-Geffard, University of Reims Champagne-Ardenne / UMRI Unité Stress Environnementaux et BIOSurveillance des milieux aquatiques; a. chaumot, Irstea / UR MALY Laboratoire Ecotoxicologie; A. Jaffal, University of Reims Champagne-Ardenne / UMRI Unité Stress Environnementaux et BIOSurveillance des milieux aquatiques; I. charron; M. Cosin Ponce, University of Reims Champagne-Ardenne / UMRI Unité Stress Environnementaux et BIOSurveillance des milieux aquatiques; A. Geffard, Université de Reims Champagne Ardenne / Interactions Animal-Environnement (IAE); H. Queau, A. Francois, Irstea centre de Lyon Villeurbanne / UR MALY Laboratoire Ecotoxicologie; O. Geffard, Irstea / UR MALY Laboratoire Ecotoxicologie

Among freshwater species intensively used in ecotoxicology, *Gammarus fossarum* is a relevant test species. In addition to its sensitivity towards contaminants, this species is a common shredder which plays a major role in leaf litter breakdown processes. Many sub-individual and individual responses have been proposed in gammarids in order to monitor and predict effects of chemical compounds on water quality. In this framework, energetic metabolism variations appear to be a good predictive tool to detect physiological disturbance of organisms linked to ecosystem quality. Indeed animal survival depends on the availability of metabolic energy necessary to ensure maintenance, growth and reproduction. Among biological processes to access energy, digestive capacities appear sensitive to contamination stress. In recent studies, based on the use of one reference population, reference and threshold values for digestive enzymes proposed as biomarkers were defined. In the same way, we described link between digestive changes and reproductive impairments. So digestive capacities appear as potential ecologically relevant endpoints to provide information on the consequences likely to occur at the highest hierarchical levels of organization (population). However the use of only one experimental population is not representative of biological diversity. In this way, it appears necessary to precise the between-populations variability of these enzyme activities. Among more than 40 sites investigated, 8 populations of *Gammarus fossarum* considered as reference were selected. On these populations a double approach was applied. In a first step, the basal level of digestive enzyme activities were studied after an acclimation of organisms to similar laboratory conditions. In a second step, the pattern of digestive capacities modulation in the 8 populations exposed at a similar stress (trophic stress) were considered. This second step aims to identify a potential difference of sensitivity between the eight populations. The results of this preliminary study, underlying changes in digestive enzymes activities, will be discussed according to environmental parameters which could be implied (different sources of food according to the site) but also concerning the potential consequences on the reference and threshold values define previously via one control population. **Keywords:** *Gammarus fossarum*, digestive enzymes, inter-populations variability

##### Natural variability of some biomarkers in the macro-zoobenthos of streams: dependence on life stage and environmental factors

M. Vighi, University of Milano / Earth and Environmental Sciences; R. Giacchini, University of Milano Bicocca / Department of Environmental and Earth Sciences DISAT; P. Parenti, University of Milano Bicocca / Earth and Environmental Sciences; L. Scardueli, University of Milano Bicocca / Earth Environmental Science

One of the major problems for the use of biomarkers in ecotoxicology is understanding if the measured responses are determined by the effects of stress factors or lie within the natural variability range produced by the effect of environmental parameters. In a previous work, the natural variability of enzymatic levels, measured in some freshwater invertebrate taxa sampled in pristine rivers, was proved to be relevant across both space and time. In this work, the experimental design was improved by considering different life stages of the selected taxa and by adding the measure of some more environmental parameters. The work aimed at evaluating the variability of some enzymatic biomarkers measured in freshwater benthic invertebrates collected in pristine alpine streams in order to limit any potential anthropic influence. The experimental design considered: sampling sites in two different rivers; eight sampling dates covering the whole seasonal cycle; four taxonomic groups (Perlidae, Baethidae, Heptageniidae, Hydropsychidae) present in almost all samples; three to four different life stages considered for each taxonomic group; four enzymes: Acetylcholinesterase, Glutathione-S-transferase, Alkaline phosphatase, and Catalase. Biomarkers levels were related to several environmental parameters (temperature, pH, conductivity, oxygen level, nitrogen and phosphate concentrations, metals and metalloids concentrations), to verify any kind of dependence. Data were elaborated using multivariate statistical methods. Natural variability of enzymatic levels was found to be relevant across both space and time.

The results of this work proved that great care should be paid when interpreting experiments in which biomarkers levels are measured and compared among sites or dates; further research is needed to understand how the natural variability of biomarkers could be accounted for and managed in ecotoxicological studies.

##### Off-site impacts of wildfires - sub-lethal biomarker responses of *Gambusia holbrooki* to pyrolytic contamination

V. Silva, Universidade de Aveiro / Department of Environment and Planning and the Centre for Environmental and Marine Studies CESAM; I. Campos, Universidade de Aveiro / Department of Environment; B. Nunes, CESAM University of Aveiro; J.L. Pereira, University of Aveiro / Department of Biology and CESAM; P. Pereira, Department of Biology and CESAM; J. Keizer, Department of Environment Centre for Environmental and Marine Studies CESAM University of Aveiro Aveiro Portugal; F. Goncalves, University of Aveiro CESAM / Department of Biology; N. Abrantes, University of Aveiro / CESAMDAO

In the last few decades, the number of wildfires has markedly increased in Mediterranean Europe, including in Portugal. Given both the nature of forestry activities, and the fire-propitious meteorological conditions due to climate change, it is expected that the number of occurrences and the burnt area in these countries will further increase. Wildfires have immediate and serious social, economic and environmental consequences. Besides all the direct effects of wildfires, it is recognized that wildfires can be a source of contaminants to downstream water bodies. In fact, pyrolytic substances, such as polycyclic aromatic hydrocarbons (PAHs) and metallic elements, associated to ashes and sediment loads, can reach the nearby aquatic systems by surface runoff. To address the potential ecotoxicological effects posed by such compounds, the present work was focused on the effects by pyrolytic compounds in the fish *Gambusia holbrooki*. Two samples were tested: a post-fire runoff sample (from a high severity wildfire on a eucalypt plantation) and surface water from the burnt catchment outlet, both collected during the first rains after the wildfire. Each sample was tested at two dilutions: 50% and 100% (original sample). Exposition had a duration of 120 h. Biochemical sub-lethal responses of *G. holbrooki* were evaluated in order to find early-warning signals of exposition to PAHs and metals. Therefore, the following battery of biomarkers of oxidative stress was applied: catalase (CAT), glutathione peroxidase (GPx), glutathione reductase (GR) and glutathione-S-transferases (GSTs). Acetylcholinesterase (AChE) activity and lipid peroxidation (LPO) were also assessed. These biomarkers were analyzed on heads, gills and liver tissues. Biochemical results provided further understanding of the sub cellular effects of pyrolytic substances contamination on a top food chain species, allowing to better understand the toxicity pathways and anticipate effects on fish populations after an input from a burnt area, as well as, in a more integrative approach, to obtain a more realistic risk assessment of the off-site effects of wildfires on aquatic systems. **Key-words:** off-site effects of wildfires, *Gambusia holbrooki*, biomarkers.

##### From waterborne contaminants to subcellular biomarkers, tissue bioaccumulation, and mussel health: Tracking the effects of waterborne metals throughout the biological hierarchy

A. de Souza Machado, Leibniz Institute of Freshwater Ecology and Inland Fisheries / Ecophysiology and Aquaculture; S.M. Wood, University of Toronto / Department of Physical and Environmental Sciences; A. Bianchini, Universidade Federal do Rio Grande - FURG / Instituto de Ciências Biológicas; P.L. Gillis, Environment Canada / Aquatic Contaminants Research Division

One of the key knowledge gaps in ecotoxicology is the linkage between exposure to harmful contaminants and the cascade of effects that occur through the biological hierarchy. Thus, the present study investigated the relationships between water chemistry (water composition and waterborne metals), subcellular biomarkers (oxidative stress and detoxification biomolecules), an index of biomarker response (IBR), tissue bioaccumulation biomarkers (gill metal and major ion concentrations), and organism general health biomarkers (gonadosomatic index and condition factor) in wild freshwater mussels from Grand River (ON, Canada). Canonic correlation revealed that water chemistry (physic-chemistry and metal concentrations) was the main factor driving all levels of biological responses analyzed (biomolecules to whole organism), explaining 86% to ~100% of variability. Also, a correlation was found between waterborne metals and gill metal content ( $r=0.92$ ,  $N=256$ ). Even though water chemistry and biological responses were highly correlated, the levels of individual inorganic contaminants did not exceed Water Quality Guidelines for aquatic life. Thus, biological damage would not be anticipated based solely on water chemistry (i.e. individual inorganic contaminants). However, chronic exposure to the complex contaminant mixture appears to have resulted in several effects. Subcellular and general health biomarkers detected environmental contamination, with variability 55-67% explained by changes in gill metal bioaccumulation, though levels of organic contaminants were not examined. However, IBR did not agree with the environmental metal contamination or urban proximity. Also, subcellular and general health biomarker responses integrated the various environmental stressors and were not significantly correlated. While biochemical biomarkers reflected the exposure gradient of urban-related contaminants, general health biomarkers better

reflected waterborne metal levels. This examination of multiple parameters and endpoints (e.g. water chemistry, tissue and organism biomarkers) provides insight into the relationships among the observed biological effects and the threat that poor water quality poses to these sentinel organisms. Finally, we propose an alternative index combining water physico-chemistry, waterborne metals and biomarkers to integrate environmental health in a broad scope, and to link water chemistry to responses at different levels of biological organization.

#### MOPC05

##### **Are transcriptomic biomarkers an added value for sediment-contact bioassays with higher plants?**

A. Brinke, German Federal Institute of Hydrology; G. Reifferscheid, Biochemistry and Ecotoxicology; R. Klein, Trier University; U. Feiler, Federal Institute of Hydrology; S. Buchinger, Federal Institute of Hydrology / Department G Biochemistry Ecotoxicology

In sediment-contact bioassays with higher plants usually sediment-bound pollutant induced changes are assessed on a macroscopic scale. As for all biotests the chemical cause for effects remains unknown. Moreover, low concentrations of contaminants can often not be detected. This situation raises the question if classical test systems can be worthwhile enhanced by transcriptomic biomarkers to bridge the knowledge gap between cause and effects, and thus link results from analytical chemistry and ecotoxicological bioassays, as well as to detect small concentrations of bioavailable contaminants. To assess dose-dependent changes, a test protocol for a sediment-contact bioassay with rice was developed. By means of DNA-Microarrays, candidate transcriptomic biomarkers for sediment-contaminations with cadmium and arsenic were identified. Obtained data were verified by means of qPCR. Rice plants were exposed on artificial-sediments at arsenic concentrations from 5 to 15 mg kg<sup>-1</sup> and cadmium concentrations from 1 to 400 mg kg<sup>-1</sup>. Inhibition of root and shoot elongation were assessed as classical macroscopic toxic endpoints. Roots proved more sensitive than shoots. EC<sub>50</sub> values were assessed as As 13 mg/kg<sup>-1</sup> / Cd 408 mg/kg<sup>-1</sup> for roots and 24 mg/kg<sup>-1</sup> / Cd 477 mg/kg<sup>-1</sup> for shoots. By means of DNA-Microarray analysis with RNA from root tissue, a subset of transcripts was identified as candidate transcriptomic biomarkers. Hence, root samples (3 time independent exposures with 4 biologically independent replicates each) were exposed at concentrations around and below the EC<sub>50</sub> (As 11/15 mg/kg<sup>-1</sup> / Cd 30/400 mg/kg<sup>-1</sup>) to assess effects at low and high concentrations of sediment compounds. Gene expression profiles of exposures were compared to those of references by means of three statistical methods (SAM; LIMMA, T-Test). The list of candidate biomarkers differed between the three statistical methods which were used for data evaluation. In order to define biomarkers which are not dependent from the underlying statistics only genes (n) occurring in all of the three candidate-lists were chosen for further evaluation. Arsenic induced measurable dose-dependent changes on the macroscopic and the transcriptomic level. Cadmium induced only low dose-dependent changes on the macroscopic level, while clear changes on the transcriptomic level were assessed.

##### **Consequences of adaptation of gammarids to chronic metallic exposures: alterations of biological functions**

J.D. Lebrun, Irstea; L.C. Fechner, Irstea Antony / UR HBAN; N. Urien, Irstea; I. Friedel, Irstea Antony; E. Gismondi, Laboratory of Animal Ecology and Ecotoxicology; J. Thome, Liege University / Laboratory of Animal Ecology et Ecotoxicology

One of the major issues in ecotoxicology is to link the exposure of aquatic organisms to biological responses. To date, the practical usefulness of biomarkers is limited because of their development in short-time exposure conditions and often, their transient response. Indeed, organisms are generally able to adapt to low environmental contaminations. However, adaptation processes generate additional energetic costs to counteract damages of toxics, at the expense of other biological functions. Thus, characterizing changes in biological traits caused by chronic exposures at the individual level offers interesting alternatives for risk assessment. Because of their ubiquity and ecological roles in freshwaters, gammarids are suitable candidates for such ecotoxicological studies. This study aims at assessing the consequences of adaptation of *Gammarus pulex* to chronic metallic exposures. During a 3-month-exposure, gammarids were artificially adapted at environmentally realistic concentrations of Cd, Pb or Cu (0.25, 5 or 1.25 µg/L respectively) in aquatic microcosms. To investigate the cost of adaptation on some biological functions, different traits were monitored, i.e. respiration, locomotion, feeding rate and digestive activities, and compared at the beginning and end of long-term exposures between naïve and artificially-adapted organisms. Results show that respiration and locomotion were still impacted in gammarids exposed to Cu for 3 months in the same extent as naïve organisms, likely due a persistent toxicity of Cu. Inversely, inhibitive effects of Cd and Pb on these traits disappeared at the end of exposures, suggesting an acquisition of tolerance for these metals. For all tested metals, chronic exposures of gammarids led to a decrease in their feeding rate associated with changes in the composition of ingested leaves. Concerning digestive activities, no effect of Cd was observed in artificially-adapted gammarids. By contrast, β-glucosidase and N-acetyl-β-glucosaminidase activities were specifically inhibited by Pb and Cu respectively, and β-galactosidase activity was inhibited by both metals. To conclude, the adaptation of *G. pulex* to chronic metallic pressures has a cost for individuals, resulting in alterations of biological functions.

Besides, obtaining biological responses, common to metals or specific to a considered metal, supports the development of biomarkers that could make evidence for long-term impacts of metals on the health of organisms.

##### **Molecular mechanisms of Retinoic Acid isomers in zebrafish eleutheroembryos**

E. Oliveira, IDAEA- CSIC / Environmental Chemistry; M. Casado, Environmental Chemistry; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; C. Barata, CSIC / Environmental Chemistry; B. Pina, IDAEA-CSIC / Environmental Chemistry

The zebrafish is a established alternative test model for developmental toxicity testing. The normal vertebrate development requires appropriate amounts of Retinoic acid (RA). All-trans retinoic acid (atRA) and 9-cis retinoic acid (9cRA) are potent metabolites of Vitamin A and operate by affecting gene expression through the retinoic acid metabolic pathway. atRA or 9cRA can bind to retinoic acid receptors (RARs) and the 9cRA isomer bind to retinoid X receptors (RXRs) with more affinity. The exogenous application of retinoid isomers to zebrafish is considered to have deleterious effects of varying magnitudes through Fish developmental stages. In this study, we report both phenotypic and transcriptomic effects of zebrafish eleutheroembryos exposed RA isomers for 24h and 72h. Nevertheless at sub-lethal concentrations the both RA isomers showed a differential regulation for 3623 features (2-Fold,  $p < 0.01$ ). The transcriptomic analyses reveal profiles describing different patterns, which allow individualizing the action of both isomers through the time. No difference in isomer stability was detected during the period of exposure in embryo water. We concluded that the 9cRA response appears to be deactivated upon time, probably related to either a specific, intracellular processing of the molecule or to a genetic negative feed-back, and that the presence of any compound masking or anyway interfering with their effective levels may cause harmful effects to developing vertebrate embryos. In conclusion, our data suggests that retinoid effects on early embryonic zebrafish development are stage-specific and is related in particular to the neuronal system behaviour. Also, the regulation of the Vitamin A dietary intake may be a special concern for future studies on the development of zebrafish eleutheroembryos.

#### MOPC08

##### **Genotoxicity assessment of environmental samples under the influence of textile discharges in Salmonella/microsome assay and Fpg-modified comet assay**

F.I. Vacchi, Faculty of Pharmaceutical Sciences; J.A. Vendemiatti, University of Campinas; V. Brosselin, Université de Lyon / ENTPE; S. Bony, Université de Lyon; A. Devaux, Université de Lyon-ENTPE; G.d. Umbuzeiro, FACULTY OF TECHNOLOGY -UNICAMP / LEAL

Surface water and effluents under the influence of textile discharges can exhibit mutagenic activity. In ecotoxicology, *in vitro* genotoxicity testing often relies on prokaryotic organisms such as in the well standardized Salmonella/microsome assay (Ames test). Many studies have demonstrated that primary DNA damage measurement with the comet assay represents a very early and sensitive genotoxicity biomarker in aquatic species. For *in vitro* studies, fish cell lines are considered an interesting eukaryotic model retaining specific fish physiological characteristics. The aim of this study was to measure the genotoxic responses of environmental samples under the influence of textile discharges in Salmonella/microsome assay and in Fpg-modified comet assay. Samples were collected in Piracicaba River upstream and downstream the discharge of Carioba Wastewater Treatment Plant treated effluent and in Quilombo River at Americana city, São Paulo State, Brazil. Organic compounds were extracted from samples by liquid-liquid using dichloromethane and methanol. Salmonella/microsome assays were done using TA98 and YG1041, with and without exogenous metabolic activation (S9). The Fpg-modified comet assays were done after a 24h-exposure of the liver fish cell line RTL-W1. In the Ames assay, higher mutagenicity was detected in strain YG1041 than in TA98, especially with S9; except for Piracicaba River upstream, which was more mutagenic without S9 in YG1041. The genotoxic potential measured by the comet assay was in the same range with and without the enzyme Fpg, except for Piracicaba River upstream, indicating in this case the prevalence of oxidative DNA lesions. Mutagenicity of Piracicaba River upstream was lower than the other sites and presented a different profile indicating the presence of compounds that cause oxidative damage and does not require S9 to become mutagenic. After the discharges, Piracicaba River becomes more mutagenic and the genotoxic profiles were similar among them and different from upstream. Comet assay was more sensitive than the Ames test to evaluate the genotoxic potential of the samples but these two tests are measuring different types of DNA damage, so they should be considered as complementary. *Acknowledgement:* The authors thank Fapesp (2008/10449-7 and 2012/13344-7) for the financial support and Drs. L. Lee and N. Bols (Waterloo University, Canada), for their gift of RTL-W1 strain.

##### **Using the zebrafish embryo model to assess potential health effects associated**

#### with indirect potable reuse water

E. Lawton, Brunel University / Institute for the Environment; P. Antczak, University of Liverpool / Institute of Integrative Biology; R. Evans, K. Subramaniam, Brunel University / Institute for the Environment; F. Falciani, University of Liverpool / Functional Genomics; S. Jobling, Institute for the Environment; E.J. Routledge, Brunel University / Institute for the Environment

The world's growing population is causing an ever increasing demand for clean safe drinking water. In some countries suitable sources of drinking water are becoming scarce and will not be able to satisfy future demand. Consequently, there is a need to find alternative sources of water that can be used for potable supply or to augment current sources. Advanced water treatment methods are now being examined to investigate whether treated domestic sewage effluent can be treated to drinking water standards and discharged near a drinking water abstraction point; a process known as Indirect Potable Reuse (IPR). The aim of this project was to investigate health effects associated with developmental exposure to IPR water at the various stages of treatment using zebrafish embryos. Embryos reared in water at different stages of the treatment process were observed for developmental abnormalities, and differences in gene expression (compared to an aquarium water control) were used to establish both the nature and persistence of these effects along the treatment process. In addition to the embryo assays, passive sampling devices, Pharmaceutical Polar Organic Integrative Sampler (Pharm-POCIS) were deployed over eight, four week periods to collect composite concentrated samples of some of the contaminants present in the effluent. These concentrated extracts were then used in *in vitro* assays; the yeast estrogen screen (as a measure of estrogenicity in the water samples) and an ELISA to measure the inhibition of prostaglandins (an indirect measure of inhibitors of cyclooxygenase activity). We compared our results of the bioassays with the large body of chemical analysis data recorded over a number of years from each of the treatments. The developmental exposures highlighted a low frequency of consistent abnormalities to the heart and spine, and also a lack of pigmentation. Gene expression analysis demonstrates the age of the embryo to have the greatest influence on global gene expression as opposed to the treatment. Single genes of interest included the cytochrome P450 and somatolactin beta. Some of the pathways disrupted included tryptophan metabolism and melanogenesis which was consistent with observations of some embryos devoid of pigment. The extracts from less treated effluent inhibited prostaglandin production and had estrogenic activity, however following reverse osmosis both prostaglandin inhibition and estrogenicity were greatly reduced.

#### MOPC10

##### Visualising compound distribution in zebrafish embryos/larva: the effect of lipophilicity

C. de Koning, Radboud University Nijmegen / University Medical Centre; M. Beekhuijzen, WIL Research Europe BV / Toxicology; M. Tobor-Kaplon, WIL Research Europe B.V. / GET; B. van de Waart, WIL Research Europe BV / In vitro and Environmental Toxicology; H. Emmen, WIL Research Europe BV / Toxicology

Zebrafish embryos are considered a new promising alternative animal model for developmental toxicity studies. Their organogenesis is rapid, embryos are transparent, and this model is not regulated by current legislations on animal welfare up to 120 hours post fertilization (hpf). It is now proposed to be included in the ICH guideline on reproduction toxicity. The predictability of the zebrafish embryo model, however, is highly influenced by compound uptake and thus internal exposure of the embryo and larva. Therefore, the advantages of using zebrafish embryos are counterbalanced by uncertainties about internal exposure and related sensitivity of the system. As compound uptake is likely to be influenced by lipophilicity, this study focusses on investigating its effect on compound distribution within the zebrafish embryo. The effect of lipophilicity was investigated for a total of seven dyes with a wide range of logP values, from which Schiff's reagent (logP: -4.63), Cresyl fast violet (logP: 3.5), and Sudan III (logP: 7.5) are selected for presentation. The use of dyes made the compound uptake and distribution within the embryo and larva visible to the eye. Each compound was tested in forty zebrafish embryos, which originated from two different batches and multiple parents. The exposure period was 96 hours, starting at 4 hpf. Every 24 hours pictures were taken for the evaluation of compound uptake. The pictures taken from embryos exposed to Schiff's reagent show minor pink colouration of the yolk sac, while the purple colour within the embryos exposed to Cresyl fast violet is apparent. The most apparent colouration of embryos is observed after exposure to Sudan III, which shows a red glow within the whole embryo and larva. From these observations it can be concluded that higher lipophilicity results in higher compound uptake by the zebrafish embryo.

#### MOPC11

##### Identifying genes in the oxidative stress cascade activated through the Nrf2-Keap1 / electrophile response element in zebrafish

A. Foreman; D. Studholme, University of Exeter; T. Kudoh, University of Exeter / Biosciences College of Life and Environmental Sciences; C.R. Tyler, Biosciences College of Life and Environmental Sciences

Oxidative stress is a common toxicological response to chemical and material insult with the production of reactive oxygen species leading to toxic effects induced at both DNA and protein levels. In response to oxidative stress, antioxidant genes are up-regulated through the Nrf2-Keap1 pathway that is highly conserved across

animal phyla. Under electrophilic insult, the transcription factor Nrf2 is released from Keap1 and binds to a cis-acting electrophile response element (EpRE) to initiate gene transcription. EpRE sequences have been identified in mammalian species, but little is known currently about functional EpRE sequences in fish. In this study, a bioinformatics approach was used to identify the EpRE in promoter regions of both human and zebrafish genes. A Hidden Markov Model (HMM) was created based on the mammalian EpRE positional weight matrix (PWM) obtained from the JASPAR database and this was searched against human and zebrafish genomes. For the human genome search, the system accurately predicted the functional EpRE sequences for a selection of genes that have previously been identified through experimental methods. A known functional EpRE region in zebrafish Glutathione-S-transferase Pi (GSTpi) was then used as a threshold score and all genes in the zebrafish genome with a score exceeding this were identified and analysed further. Using DAVID, biological pathway analysis was conducted to compare overrepresented pathways from the two outputs and this identified ion regulation to be over-expressed in both the human and zebrafish EpRE containing genes. As metal ions have the potential to produce free radicals, the regulation of ions is essential to prevent an oxidative stress response. Subsequently, the zebrafish gene list was filtered and compared with results generated from next generation sequencing for exposures of zebrafish embryos to silver nanoparticle, ion and bulk materials known to exert toxicity through an oxidative stress response. Identified genes included GSTpi, Glutathione cysteine-ligase modifying subunit, Heme-oxygenase 1 and Ferritin heavy-chain 1, all recognized targets of Nrf2 in mammals and involved in antioxidant defence. Whole-mount in-situ hybridisation in zebrafish embryos is now being undertaken with these identified genes in order to confirm regulation by Nrf2 through exposure to different inducers of oxidative stress.

#### MOPC12

##### Xenobiotic metabolism in zebrafish embryos: enzyme activity in early life stages

B. Schultz, Ecotoxicology; J.C. Otte, BASF SE; D. Vogel, E. Fabian, BASF SE / Experimental Toxicology and Ecology; E. Salinas, BASF SE

Early life stages of the zebrafish (*Danio rerio*, zf) are increasingly used as model organisms for drug discovery, early teratology screening and chemical testing strategies in (eco-) toxicological assessment (e.g. OECD TG 236; 210; 234). The applicability domain for zf embryos is still expanding due to the many advantages of this biological model (for example fast, external, and translucent development) as well as increasing concern for animal welfare. However, for a well-balanced understanding and interpretation of a (toxicity-) study outcome, it is essential to have knowledge about the potential and extent of xenobiotic metabolism in the system used. Current literature points towards gene activity of several xenobiotic metabolizing enzymes in very early developmental stages, however, evidence of enzyme activity is lacking in most cases. In this work the activities of representative phase I and phase II metabolizing enzymes (glutathione-S-transferase, esterase, alcohol dehydrogenase, aldehyde dehydrogenase, N-acetyl transferase 1) were monitored by model substrate transformation using photometric and high pressure liquid chromatography (HPLC) techniques. Six different stages of zf development (between 2.5 hours post fertilization (hpf) to 120 hpf), were investigated. Two main questions were addressed: first, do zf early life stages demonstrate xenobiotic metabolism in a relevant manner for toxicity testing? And second, does this enzyme activity significantly differ during ongoing development? Activities above the methodological level of detection were demonstrated for the enzymes glutathione-S-transferase (GST) and esterase, respectively in all investigated developmental stages. The results with other enzyme systems were inconclusive and methodological difficulties associated with isolating subcellular fractions from zebrafish embryos are discussed. Overall, zf embryos do possess measurable xenobiotic metabolism in early life stages.

#### MOPC13

##### Biodegradation studies of a series of novel L-Phenylalanine derived Ionic Liquids by a modified Closed Bottle Test protocol including targeted synthesis of persistent metabolites

A.E. Jordan, Chemical Sciences; K. Kümmerer, University of Leuphana / Sustainable Chemistry and Material Resources; A. Haiß, Leuphana University Lüneburg / Institute for Sustainable Chemistry and Environmental Chemistry; J. Westphal, Leuphana University Lüneburg / Technology and Management; M. Spulak, Charles University / Centre for New Antivirals and Antineoplastics, Department of Inorganic and Organic Chemistry, Faculty of Pharmacy; D. Coleman, M. Ghavre, Dublin City University; N. Gathergood, Dublin City University / School of Chemical Sciences

The association of Ionic Liquids (ILs) with green chemistry has increased substantially over the past decade concurrent with the upsurge in their use in industrial and academic applications. However, early generations of ILs such as the butyl-methylimidazolium class, have shown to be recalcitrant to biodegradation, calling for the need to examine ILs for biodegradability. The biodegradability of Ionic Liquids has become increasingly more important as a point of characterisation

of ILs. The biodegradation information obtained allows an insight to be gained into how an IL will interact with the environment should it ever enter the environment. The information gained from biodegradation studies also allows for rational design of performance chemicals and should help prevent the synthesis of persistent organic pollutants - the “**Benign by Design**” concept. Examining ILs for biodegradation is also reinforced by the 10th principle of green chemistry - **Design for Degradation**. Biodegradation can be measured by a number of prescribed test methods including those supported by the Organisation of Economic Co-Operation and Development (OECD) and the International Organisation for Standardisation (ISO). Problems that exist in the application of these test methods include that a chemical can be classified as readily biodegradable yet still persist as an environmentally persistent metabolite fragment. Modifications to the test methods allow results to be obtained that were not initially accommodated for. In this presentation the results of the biodegradation screening of a series of L-Phenylalanine derived ILs will be presented. Only halide ILs have been screened so as to remove the variability of biodegradable anions. A modified CBT has been employed to analyse persistent chemical fragments that do not readily biodegrade and that are present at the end of the 28 day biodegradation screening. Comprehensive analysis by LC/MS of the residues remaining in the CBT vessel post testing to elucidate the structures of persistent metabolite fragments was conducted. Not all ILs tested gave a persistent fragment and these examples are of paramount importance for designing next generation ILs as they present a platform upon which readily/ultimately biodegradable ILs can be designed from. Avoiding persistent cation/anion fragments as determined by metabolite studies and employing the identified readily biodegradable building blocks presents a innovation in IL design.

#### MOPC14

##### **Investigation into the biodegradability of various hydrocarbon solvents**

C. Hughes, Shell International Limited / Shell Health; G.F. Whale, Shell Health / Shell Health; C. Mead, Ecotoxicology dept

Hydrocarbon solvents are petrochemicals used in a wide range of industrial and consumer applications globally. These products consist of many different hydrocarbon constituents and are described as UVCB substances. They are most commonly derived from the processing of crude oil, but other varieties, such as synthetic ‘isoalkanes’ and solvents derived by the Fischer-Tropsch, or ‘Gas-to-Liquid’ (GTL) process, also exist. Although different solvents may share similar performance properties and be used in similar applications, their composition varies depending on the origins of the substance. In this presentation studies have been undertaken to assess whether compositional changes are reflected in the biodegradability of solvents. The OECD 301 A-F series of tests are currently used to assess the ready biodegradation of chemicals in freshwater. The results of these tests are used extensively both within a regulatory context and to support marketing claims on product biodegradability. However, they have their limitations, particularly when they are used to assess the biodegradation of complex and/or poorly water soluble substances. Previous investigations into the biodegradability of GTL fuel and base oil have highlighted these issues. The 301F method was identified as better suited for testing GTL products than 301B. Analysis of vessels at the start and the end of the test indicated that a significant amount of material was lost by abiotic means in the 301B test. This was attributed to the aeration stripping the test substance from the water. The 301F test was found to limit such losses. Based on these findings, the testing of GTL solvents followed a similar methodology. GTL solvents consist predominantly of n-alkanes and simply branched isoalkanes. This suggests they would be particularly susceptible to biodegradation based on the generally accepted view that hydrocarbon classes can be ranked in the following order of biodegradability: n-alkanes > branched alkanes > low-molecular-weight aromatics > cyclic alkanes. For comparison purposes a series of tests was conducted, including hydrocarbon solvents derived by other means. The results of these studies are used to draw conclusions about the biodegradability of hydrocarbon solvents relative to one another. In addition, the challenges associated with measuring biodegradability using the currently accepted methods are further illuminated.

#### MOPC15

##### **Removal of pharmaceutical wastewater containing erythromycin under anaerobic conditions**

Z. Cetecioglu, Istanbul Technical University / Environmental Engineering; B. Ince, Bogazici University / Institute of Environmental Sciences; M. Gros; S. Rodriguez-Mozaz, Institute for Water Research (ICRA) / Water Quality; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research; D. Orhon, O. Ince, Istanbul Technical University  
In this study, the chronic effect and biodegradability characteristics of erythromycin were assessed under anaerobic conditions. For this purpose a lab-scale anaerobic sequencing batch reactor was operated in a sequence of different phases with gradually increasing erythromycin doses of 1,65 – 8,5 mg/L, for more than five months and conventional parameters such as COD, VFA, methane generation were monitored with antibiotic concentrations in wastewater and sludge. Also methanogenic activity of the sludge was determined during experiments. The results revealed that anaerobic treatment is suitable for pharmaceutical industry wastewater up to 8,5 mg/L of erythromycin concentration. 8,5 mg/L and more than this concentration has a terminal/lethal effect on the

microbial community under anaerobic conditions, which caused the inhibition of substrate/COD utilization and biogas generation and lead to a total collapse of the reactor. The adverse long-term impact was quite variable for fermenting heterotrophic and methanogenic fractions of the microbial community based on changes inflicted on the composition of remaining/residual organic substrate.

#### MOPC16

##### **Evidence of enhanced degradation of Prometryn in OECD 307 guideline studies including viable crop root systems**

C. Gougoulis, Syngenta Ltd / Product Safety; P. Thomas, CEHTRA SAS / Ecotoxicology and Risk Assessment; L.H. Hand, Syngenta Limited / Product Metabolism; I.W. Oliver, Keele University / Physical Geographical Sciences; I. Bramke, Syngenta Ltd / Product Safety

The environmental fate and behavior of crop protection products (CPPs) in soil is a key part of the regulatory approval process. It is becoming increasingly clear that key contributors to microbial degradation present in the field are not represented in OECD307 guideline studies (i.e. phototrophic soil surface communities and below-ground communities thriving near roots). This may be part of the reason why dissipation rates are often faster in the field than in the laboratory. The purpose of this project was to integrate viable crop-root systems (ryegrass, red clover, hot pepper) into an OECD307 test system to evaluate any differences in the degradation of a model pesticide, compared to the ‘bare soil’ OECD307 standard. A second control was included to account for any impacts of dynamic temperature or moisture resulting from incubation under a light-dark cycle. Phototrophic soil surface communities were deliberately excluded. All planted and control systems were set-up and sampled in triplicate at four time-points after T0. The model compound, <sup>14</sup>C-prometryn, was applied to the soil at field rate. Residues were extracted using solvent and quantified by LSC, whilst radioactivity in post-extraction solids, including all plant material, was quantified by combustion and LSC. Volatiles and CO<sub>2</sub> were trapped in NaOH to complete the mass balance. Extracts were and analyzed by HPLC with radiodetection to quantify the prometryn concentration. All three chosen crop plants formed and maintained branched root networks of a healthy appearance for at least 63 days of incubation. Compared to the OECD307 control, the time taken for 50% dissipation of prometryn was halved in the systems planted with ryegrass and hot pepper and reduced by a third in the presence of red clover. No significant uptake of radioactivity into the plants was observed. Our work shows that the crop-root networks of different plant groups (monocots, dicots, legumes) are capable of increasing CPP degradation in closed laboratory systems. Further work will be required to investigate the effect on other model compounds and reveal how the microbial communities in laboratory soil systems are altered when crop-root systems are introduced. Based on our data, greater environmental realism is conferred by inclusion of crop plant-root systems, which could be of significance for the environmental risk assessment process.

#### MOPC17

##### **Comparing laboratory based estimates of dissipation rates for five pharmaceuticals with in situ dissipation rates**

J. Klaminder, Ecology and Environmental Science

Pharmaceuticals included in treated wastewater effluent pose a potential threat to aquatic ecosystems, as they may affect non-target organisms in recipient waters. Predictions from laboratory experiments suggest that their dissipation in natural aquatic systems may last at a time-scale ranging from days to month. To what extent standardized laboratory assays designed to detect the biodegradability of chemicals, can be used to predict the dissipation of pharmaceuticals in more complex natural ecosystems environments are rarely tested. In this study we conduct a large-scale experiment where we applied five common pharmaceutical contaminants (*Diphenhydramine*, *Oxazepam*, *Trimethoprim*, *Diclofenac* and *Hydroxyzine*) to two functional aquatic ecosystems, including natural fish and invertebrates. One of the ecosystems was covered with a tarp to completely remove photodegradation processes. The main objective was to measure the dissipation rates of the drugs from the water phase into the food web (fish and invertebrates) or sediments and compare the results with dissipation rates estimated from laboratory assays. Here, we present for the studied pharmaceuticals; i) *in situ* dissipation rates; and ii) quantitative estimates of the relative importance of photo- and microbial degradation in natural waters. The results are compared with similar estimates derived from laboratory incubations. Based on our findings, we discuss the ability to predict the dissipation of pharmaceuticals from aquatic systems using laboratory assay estimates.

#### MOPC18

##### **Microbial biomarkers as indicators of biotransformation rate of isotope-labelled pesticides in soil**

K.M. Nowak, RWTH Aachen University / Institute for Environmental Research Biology V; A. Miltnr; S. Andreas, RWTH Aachen University / Institute for Environmental Research; M. Kästner, Helmholtz centre for environmental research - UFZ / Department of Environmental Biotechnology  
Pesticides as anthropogenic chemicals are of high interest; since they are deliberately applied in high amounts to soils to support food crop production Chemicals entering this complex soil system may undergo various turnover processes. They can be degraded chemically, biologically by microorganisms,

immobilised in the form of non-extractable residues (NER), volatilised or taken up by living organisms. Microbial degradation is considered to be the main pathway of their ultimate detoxification. It is generally known that microorganisms can use C (and N) from an organic contaminant to synthesise their biomass compounds, for instance fatty acids (FA) and amino acids (AA). After death, these biomass compounds can be incorporated into soil organic matter (SOM) forming ultimately biogenic residues. The extraction of known microbial biomarkers from soil after addition of C isotope tracer allows an estimation of microbial activity in the biogeochemical cycling of C. Microbial biomarker analysis is thus also useful in studying the microbial transformation of labelled pesticides in soil. Therefore, we investigated biotransformation of 2,4-D, glyphosate and bentazone with the particular focus on the metabolic incorporation of the isotope label into FA and AA and their fate in soil over time.  $^{13}\text{C}$ -FA and  $^{13}\text{C}$ -AA in the living microbial biomass fraction initially increased, thereafter their contents decreased and a continuous incorporation of these biomolecules into the non-living SOM pool was observed. Total amount of the biogenic residues (44% and 21% of  $^{13}\text{C}_6$ -2,4-D and  $^{13}\text{C}_3^{15}\text{N}$ -glyphosate equivalents) and high mineralization rates of both 2,4-D and glyphosate (58% and 75% of  $^{13}\text{C}_6$ -2,4-D and  $^{13}\text{C}_3^{15}\text{N}$ -glyphosate equivalents) suggest that these pesticides were nearly completely biodegraded. However, in the case of more recalcitrant pesticides like bentazone, the incorporation of C into microbial biomass, although reported to be very low, cannot be completely excluded.

## Modelling fate & transport of micropollutants: Integration of engineered wastewater systems & natural water bodies - Blind spots & challenges ahead (PC)

### MOPC19

#### Advancements in the assessment of micropollutants through the application of broad-scale "down-the-drain" exposure modelling

K.E. Kapo, R. Vamshi, C.M. Holmes, Waterborne Environmental, Inc.; P.C. DeLeo, D. Ferrer, American Cleaning Institute  
Municipal effluent is a major exposure route for a wide range of "down-the-drain" chemicals that are treated and discharged to natural water bodies. Exposure models that focus on estimating concentrations of effluent-associated chemicals in receiving waters can serve as a valuable screening-level tool for risk assessment of micropollutants and other potential environmental stressors. In this presentation, we provide an overview of current developments, advancements and challenges in "down-the-drain" exposure modelling, with a focus on iSTREEM<sup>®</sup>, a web-based model made freely available to the public by the American Cleaning Institute ([www.istreem.org](http://www.istreem.org)). iSTREEM<sup>®</sup> provides a means to estimate concentrations of "down-the-drain" chemicals in effluent, receiving waters, and drinking water intakes across national and regional scales under mean annual and low (7Q10) flow conditions. The development and evolution of the iSTREEM<sup>®</sup> model reflects recent trends in technical, conceptual and practical aspects of "down-the-drain" exposure modelling to address current challenges and needs, such as assessment over broad geographies, incorporation of variability, and geo-referencing of modelling components. The spatial nature of the model, integrating point locations of facilities along a hydrologic network, provides a powerful framework to assess environmental risk in a spatial context. To enhance transparency and interpretation of the iSTREEM<sup>®</sup> model, a case study was conducted comparing national distributions of modelled concentrations of a variety of "down-the-drain" consumer product ingredients to available monitoring data at comparable flow conditions. The iSTREEM<sup>®</sup> model yielded generally conservative exposure estimates, which can be used to construct a conservative estimation of the distribution of chemical concentrations for effluents and streams. Recent technical enhancements and the expanding applications of iSTREEM<sup>®</sup> will be overviewed, as well as characteristics of iSTREEM<sup>®</sup> in the context of other current "down-the-drain" models. Enhancing understanding, accessibility and collaboration across the modeling landscape provides opportunity to expand and improve upon individual models and increase their acceptance as a decision-support tool.

### MOPC20

#### Towards spatially smart abatement of human pharmaceuticals in surface waters: defining impact of sewage treatment plants on susceptible functions

L. Coppens, KWR Watercycle Research Institute; A. van Wezel, KWR Watercycle Research Institute / Chemical Water Quality and Health  
For pharmaceuticals, sewage treatment plants (STPs) are a major point of entry to surface waters. The receiving waters provide vital functions. Modeling the impact of STPs on susceptible functions of the surface water system allows for a spatially smart implementation of abatement options at or in the service area of STPs. This study was performed on a nation-wide scale for the Netherlands; 345 Dutch STPs and 9 rivers from neighboring countries were included as emission points and 2,511 surface water units (SWUs) represent physical parts of the Dutch surface water network. Modeling was performed for two extreme discharge conditions. Monitoring data of 7 locations along the Rhine and the Meuse fall mostly within the range of modeled concentrations. Half of the abstracted volume of raw water for drinking water production, and a quarter of the Natura 2000 areas hosted by the surface waters, are influenced by STPs at low discharge. The vast majority of the

total impact via all Dutch STPs during both discharge conditions can be attributed to only 19% of the STPs with regard to the drinking water function, and 39% with regard to the Natura 2000 function. In conclusion, attributing water treatment technologies to STPs as one of the possible measures to improve water quality and protect susceptible functions can be done in a spatially smart and cost-effective way, using consumption-based detailed hydrological modeling.

### MOPC21

#### Modeling and Monte Carlo sensitivity analysis of 8 pharmaceuticals' occurrence in the Llobregat River (NE Spain)

Z. Banjac, CSIC / IDAEA Environmental Chemistry; A. Ginebreda, CSIC - Spanish National Research Council / Department of Environmental Sciences; R. Marcé, Catalan Institute for Water Research (ICRA) / Resources and Ecosystems; L. Boithias, Catalan Institute for Water Research ICRA; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research  
**Modeling and Monte Carlo sensitivity analysis of 8 pharmaceuticals' occurrence in the Llobregat river** Zoran Banjac<sup>1</sup>, Antoni Ginebreda<sup>1</sup>, Rafael Marcé<sup>2</sup>, Laurie Boithias<sup>2</sup>, Damià Barceló<sup>1,2</sup>  
<sup>1</sup> Institute of Environmental Assessment and Water Research (IDAEA-CSIC), Department of Environmental Chemistry, 08034 Barcelona, Spain <sup>2</sup> Catalan Institute for Water Research (ICRA), Girona, Spain  
Keywords: Uncertainty analysis, Pharmaceuticals, Modeling, Monte Carlo analysis  
The objective of the ongoing research is to model the environmental occurrence of some representative pharmaceuticals (Diclofenac, Ibuprofen, Ketoprofen, Naproxen, Azitromycin, Acetaminophen, Diltiazem and Valsartan) in the Llobregat basin and to assess its sensitivity respect to some of the parameters used. The model was constructed on the basis of the steady-state equations describing the fate of the pharmaceuticals in rivers and waste water treatment plants (WWTPs) with the aid of programming which was used for more efficient Monte Carlo uncertainty analysis. Simulation outputs are statistical distributions of predicted environmental concentrations (PECs) for each river stretch. In order to validate the model results were compared with the experimental data from the project SCARCE Consolidator. On the other hand we have estimated the sensitivity of the parameters used in the model by calculation of the corresponding sensitivity coefficients defined as  $\text{CV}_{\text{PEC}}/\text{CV}_X$  where CV are the coefficients of variation, X the parameters drug consumption. Parameters are: (M), waste water plant removal ( $R_{\text{WWTP}}$ ), linear velocity of the river (v), river flow (Q), hydraulic residence time (HRT), in stream removal (k) and predicted environmental concentrations (PECs). In order to get more precise estimation the sensitivity analysis is conducted for all stretches of the river. Predicted environmental concentrations are in good order of magnitude with reported measured concentrations (ng/L). Sensitivity analysis shows that removal in WWTPs is the most sensitive parameter in the modeling of pharmaceuticals fate in rivers and WWTPs. References: Osorio, V., R. Marcé, et al. (2012). "Occurrence and modeling of pharmaceuticals on a sewage-impacted Mediterranean river and their dynamics under different hydrological conditions." *Science of The Total Environment* 440(0): 3-13.

### MOPC22

#### Sources of uncertainty in modelling pharmaceuticals at the basin scale: an inventory across engineered and natural systems

R. Marcé, Catalan Institute for Water Research (ICRA) / Resources and Ecosystems; L. Boithias, Catalan Institute for Water Research ICRA; I. corominas, ICRA; L. Bosch, S. Gabarrón, Catalan Institute for Water Research ICRA; A. Ginebreda, CSIC - Spanish National Research Council / Department of Environmental Sciences; V. Acuña, RiE; M. Petrovic, ICRA; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research; s. sabater, Universitat de Girona  
During the last years, increasing interest has gone into chemical fate and transport models for the assessment of chemical concentrations throughout WWTP and into receiving freshwater ecosystems to assist decision-making. These models allow interpreting measured data, extrapolate to new situations, and evaluate proposed solutions for pollution issues. However, the modelling micro-pollutant research community faces a fundamental challenge: the wide range of chemicals to be considered and the emergent nature of most of them imply that few data are available to feed the models. As a result, a high degree of uncertainty is still associated with model outcomes, compromising both the heuristic knowledge gained from the modelling exercise and the potential management decisions based on the model results. Here, we assess the main sources of uncertainty in the modelling of micro-pollutants concentration across engineered-natural coupled systems, using a humanized basin in NE Spain as a paradigmatic case study. The Llobregat River Basin includes more than 40 WWTPs that discharge in the associated river network, which is a heterogeneous mosaic comprising river reaches from near pristine to highly impacted status. We built a parsimonious model aimed to predict the concentration of 10 pharmaceuticals of human use along the river network considering the following processes: 1) the apparent human consumption of the pharmaceuticals and the load received by WWTPs; 2) the removal of pharmaceuticals in the WWTPs and the load from the effluents to the river; and 3) the apparent in-stream removal during transport along the river network. We assessed the uncertainty of the predicted river concentration arising from the different terms of the model considering the most likely distribution of the values for the different parameters considered in each modelled process. Those distributions were built by mining literature and databases, inverse modelling

approaches, and formulating new empirical relationships for the removal of pollutants in WWTPs with varying technology. The results showed that while the modelling approach seems a suitable tool to advance science and management with the information already available, relevant research topics must be addressed in the following years to reduce the uncertainty of the outcomes. In particular, the uncertainty analysis pointed to the fate of pollutants in WWTP as one of the main sources of model ambiguity.

## Impact of statistical methods used in ecotoxicological studies on regulatory decisions (PC)

### MOPC25

#### Comparison of Models for Analyzing Ecotoxicity Studies

C. Teel, DuPont / Applied Statistics; J.W. Green, DuPont / Applied Statistics Group  
Several alternative statistical models for analysis of mollusc fecundity, fish early life stage mortality and size, and non-target plant emergence and growth will be compared using a collection of statistical tools appropriate for modeling many ecotoxicity studies. For mollusc fecundity, gamma-Poisson Bayesian models with several alternative underlying concentration-response shapes are compared to one another as well as to several non-Bayesian models with normal error structure. For quantal data (ELS mortality and seedling emergence), quantal regression models with Poisson or negative binomial error structure are compared to probit and non-linear regression models based on proportions. For continuous responses (e.g., size, growth rate), non-linear models with alternative concentration-response shapes and different ways to capture heterogeneous variances are contrasted. Comparisons are made with datasets from guideline laboratory studies and from simulations where the true EC<sub>x</sub> values are known. General methods for comparing approaches to modeling of ecotoxicity studies are provided and assessed for utility. The relationship between experimental design and model choice will also be explored. The possibility that no suitable regression model can be found will be quantified along with alternative approaches to handle such data

### MOPC26

#### Ecotoxicology is not normal!

E. Szöcs, Institute for Environmental Sciences; R.B. Schaefer, University Koblenz Landau / Institute for Environmental Sciences

Ecotoxicologists perform various kinds of experiments yielding to different types of data often with very small sample sizes and usually not normally distributed. Such data are in most cases analysed with traditional data analysis methods based on the normal distribution. Therefore, they try to transform their data to meet these assumptions and if this fails they refer to non-parametric approaches. Generalized Linear Models (GLM) can fit various types of distributions to data, making a transformation obsolete. However, GLMs are rarely used in ecotoxicology. We simulated two types of data: counts and proportions mimicking data that ecotoxicologists often encounter. We compared models assuming a normal distribution after data transformations (log(Ax + 1) for count data and arcsine square root for binomial data) with GLM of appropriate distributions in terms of statistical power and Type-I error. We tested for effects using Likelihood-Ratio-Tests (LRT), F tests parametric bootstrap of these models and a non-parametric approach (Kruskal-Wallis-Test). For extreme sample sizes (N = 3) and count data we found that normal and negative binomial models showed similar performances. However, with increasing sample sizes GLM showed higher power. LRT did not perform well for low sample sizes and parametric bootstrap maintained an appropriate error level. We note, that in our simulation setup (50% reduction in abundance due to treatment) the power was very low for N = 3 (< 50% for models with appropriate error level), which is a common sample size in mesocosm experiments. For binomial data the binomial GLM showed the highest power when sample sizes were extremely low. However, the differences vanished quickly with increasing sample sizes. The non-parametric Kruskal-Wallis test showed low power and was very conservative, especially with small sample sizes. Low replicated experiments are common in ecotoxicology. The power when analysing these should not be further constrained through the use of models not fitting to the data. GLMs provide equal or better statistical properties than models based on data transformations and fit to various types of data without the need of transformations. Our results may also extend to the multivariate case, where recently GLMs for multivariate data have been proposed as alternative to ordination methods. Ecotoxicologist should include GLMs into their statistical toolbox and update the respective statistical guidelines.

### MOPC27

#### Data Should NOT be Normalized to the Control for Analysis

J.W. Green, DuPont / Applied Statistics Group

A technique common in the analysis of some ecotoxicity studies is to normalize data in treatment groups to the control. In the case of quantal data (e.g., mortality, emergence, hatching), the method for doing this is sometimes referred to as Abbott's formula. The original purpose of this method was to adjust mortality data for background incidence. When this idea was first proposed in 1925, most statistical analysis was done manually, so there was a need for simple numerical calculation methods. It has also been used for continuous responses, where the object is to estimate the concentration at which a specified percent effect relative to the control mean response occurs. In this situation, there is no need to adjust for

background and the primary purpose in normalizing to the control is to modify the data so that a probit analysis (which assumes quantal data) software package can be used. Better ways to take background mortality into account or model continuous responses have been known for several decades and software is widely available to carry out these alternative methods. It will be proved not only is the analysis of normalized data theoretically unsound and unnecessary, but is misleading. In the context of several types of guideline studies, it will be shown that EC<sub>x</sub> estimates from analysis of normalized data (quantal or continuous) can over- or under-estimate the true value by a large factor when other readily available approaches provide accurate estimates.

### MOPC28

#### Considerations in selecting endpoints from ecotoxicity tests: An example using algae and cyanobacteria

J.P. Staveley, Exponent

Regulatory authorities are increasingly looking to make decisions based on an EC<sub>05</sub> or EC<sub>10</sub> endpoint, perhaps due to wide-spread criticisms of the NOEC. However, it is important to recognize the types of data suitable for EC<sub>x</sub> approaches, including understanding the limitations of the study design and the variability in the selected response parameter. In the U.S., harmonized test guidelines for pesticides and industrial chemicals for toxicity testing with algae and cyanobacteria include the EC<sub>50</sub> and the NOEC as test endpoints, and state that if the NOEC cannot be determined, the EC<sub>05</sub> is used instead. A meta-analysis of toxicity test data for algae and cyanobacteria was conducted to examine the inherent variability in the test design and the validity of a 5% effect measure. Three species of microalgae and one species of cyanobacteria were included in the analysis. The coefficient of variation (CV) and standard error (SE) were calculated for the following growth parameters at 96 hours: yield, area under the growth curve (AUGC), and growth rate. The analysis indicated that the CV varies depending on the growth parameter and is often greater than 5%. For growth rate, the control CV can be expected to be 3%–7%, while for yield and AUGC, it can be expected to be 10%–20%. For cyanobacteria, these values are even greater. The measure of variability is reduced when based on SE, which accounts for the number of replicates, but is still not consistently below 5%. There are conceptual, statistical, and risk assessment reasons why the EC<sub>05</sub> is not an appropriate endpoint for toxicity tests with algae and cyanobacteria. Concerning the statistical reasons, the results from this analysis indicate that it is not possible to reliably distinguish the effects of test substances from the control on growth responses of algae at a 5% level, and this level is even greater for cyanobacteria. The analysis confirms the contention that the appropriate value of the EC<sub>x</sub> for use in risk assessment will vary depending on the test species, measurement parameter, and test design. The path away from use of the NOEC will require a similar evaluation for all types of ecotoxicity tests, rather than an arbitrary assumption that an EC<sub>05</sub> (or other EC<sub>x</sub>) is suitable in its place. The use of the EC<sub>x</sub> requires a decision on what value of “x” is both biologically and statistically significant.

### MOPC29

#### Environmental risk assessment of diclofenac: roots of uncertainty

H. Serra; J. Garric, Irstea Lyon

In 2013, diclofenac was added to the watch list for emerging pollutants under the Water Framework Directive in order to gather sufficient information on its occurrence in European rivers. Indeed, concern arose from studies showing adverse effects in trout tissues at the low µg/L. Therefore, we reviewed 24 studies that assessed diclofenac chronic effects on freshwater species (classical and biomarker endpoints) and we propose an environmental risk assessment based on the risk quotient method (ratio PEC/PNEC). The PEC was calculated following the guideline for ERA of medicinal products for human use, whereas the PNEC was derived following the Technical Guidance Document (TGD) of ECHA. Our work aims at assessing the impact on risk assessment outcome of (i) the method used to derive the PNEC (species sensitivity distribution, SSD, or assessment factor, AF) and (ii) choice of the dataset (with or without biomarker results), in order to illustrate current hurdles in ERA procedures. Considering all data, the ERA outcome depends on the method used to derive the PNEC. The RQ is above 1 (RQ=7.5) with the PNEC<sub>AF</sub>, whereas it is below 1 (RQ=0.5 [0.04;3.7]) with PNEC<sub>SSD</sub>, although showing a huge confident interval (CI) which includes 1. In contrast, without biomarker results, the RQ is below 1, irrespectively from the method used. Biomarkers orientate clearly the regulatory decision for diclofenac. According to ECHA TGD, biomarkers should be “toxicologically relevant in term of population dynamics”. However, only 2/7 studies investigated concomitantly biomarkers and classical endpoints. Some biomarkers lacked of specificity (e.g. oxidative stress) and displayed no clear dose-dependent effect. Furthermore, we identified discrepancies in protocol design regarding histology findings (4/7 studies, e.g. grade of severity), impeding direct comparison of results. Overall, our analysis illustrates known issues related to ERA procedures such as the influence on regulatory decision of the method for PNEC derivation and the choice of dataset. The SSD provides a CI and seems more robust, whereas the use of AF is more protective and can be applied in case of few data. Biomarkers have attractive features, however, this case study highlights a need for a quality assurance for measurement of biomarker (e.g. standard protocol) and for biological linkage with higher level changes (e.g. using a suite of endpoints) in order to promote their use for regulatory purposes.

### MOPC30

#### How to obtain robust data from aquatic higher tier studies: lessons learned

P. Lopez-Mancisidor, Dow Agro Sciences LLC / Ecotoxicology; G. Meregalli, Dow AgroSciences Italia srl / Regulatory Scies & Government Aff.; N. Poletika, Dow Agrosciences / RSGAACES; I. Barber, Dow Agrosciences

The aim of this study was to re-evaluate 8 micro-/mesocosm studies in order to assess the reliability of the results to be used for the derivation of RACs based on the ecological threshold option (ETO-RAC) and/or the ecological recovery option (ERO-RAC) to be used during the registration procedure for pesticides in the EU. The Minimum Detectable Differences (MDD) calculation was selected as the statistical tool to evaluate the reliability of the endpoints derived from these studies following the recommendations of the new EFSA Aquatic Guidance Document (AGD) and Brock et al. (2014). The results and conclusions derived from this re-evaluation will be used to make recommendations for the design of further micro-/mesocosm experiments. The results obtained in the re-evaluation of the results obtained from the different micro-/mesocosm studies showed an acceptable robustness in some of them, however for some taxa (especially for some macroinvertebrates) the MDD<sub>abu</sub> values are above 100% and no clear treatment related effects could be determined because of the low power of the analysis. For one of the insecticides, the NOEC derived for *Chaoborus* spp. differs between the three studies available and the calculated MDD<sub>abu</sub> values can be used to determine which is the most reliable NOEC to be used in the risk assessment. It can be concluded that special attention should be taken during the pretreatment period to try to avoid the variability amongst the replicates that can affect the robustness of the data obtained. Other factors that should be taken into account during the design of the experiment is the sampling methodology for macroinvertebrates and emerged insects to try to optimise the number of individuals sampled. These conclusions are in line with those stated in Brock et al. (2014) and can determine the reliability of these studies for the derivation of the Regulatory Acceptable Concentrations.

### Fracking and spills: Environmental risk assessment of oil and gas exploration activities (PC)

### MOPC31

#### Impact of fracking on ambient PAH levels in a rural community

L.B. Paulik, C.E. Donald, B. Smith, Oregon State University / Environmental and Molecular Toxicology; L.G. Tidwell, Oregon State University / Environmental Molecular Toxicology; K.A. Hobbie, Oregon State University / Environmental Molecular and Toxicology; L. Kincl, Oregon State University / College of Public Health and Human Sciences; E. Haynes, University of Cincinnati College of Medicine / Department of Environmental Health; K.A. Anderson, Oregon State University / Environmental Molecular Toxicology

Unconventional natural gas drilling, or “fracking,” has increased rapidly in the U.S. in recent years. Coupled with a lack of regulation, this has raised concern about environmental and health impacts. To address this, passive air samplers were deployed in a rural Ohio community that has been heavily impacted by fracking. Trained landowners mailed samplers to Oregon State University, where they were analyzed for 62 polycyclic aromatic hydrocarbons (PAHs). Data were grouped based on distance from the sampler to the closest active fracking well. Three distance groups were created, with the “close” group < 0.1 from an active well, the “middle” group from 0.1 to 1.0 mile from an active well, and the “far” group >1.0 mile from an active well. Average PAH levels increased as samplers got closer to active wells. Sourcing ratios indicated that PAHs measured in samplers in the close group were predominantly petrogenic, while PAHs had a stronger pyrogenic signature as samplers moved farther from active wells. Quantitative human health risk assessments estimated the excess lifetime cancer risks (ELCRs) associated with exposure to measured PAH levels. For a maximum residential exposure of 24 hours/day, the ELCR decreased from 262 to 176 in a million when moving from the close to far group. All ELCRs were above the level that the U.S. EPA considers acceptable. This work suggests that fracking activity could be contributing significantly to the ambient PAH load, at levels that are relevant to human health.

### MOPC32

#### Identification and assessment of compounds contributing to acute toxicity of Oil Sands process affected water

G. Morandi, University of Saskatchewan / Department of Veterinary and Biomedical Sciences and Toxicology Centre; S.B. Wiseman, University of Saskatchewan / Toxicology Centre; k. zhang, University of Alberta; A. dos Santos Pereira, University of Alberta / Division of Analytical and Environmental Toxicology; R. Martin, Stockholm University / DIV OF ANALYTICAL AND ENVIRONMENTAL TOXICOLOGY DEPARTMENT OF LABORATORY MEDICINE AND PATHOLOGY; J.P. Giesy, University of Saskatchewan / Toxicology Center

Oil Sands process-affected water (OSPW) produced during the extraction of bitumen in the surface-mining Oil Sands industry in Alberta, Canada, is acutely and chronically toxic to aquatic organisms. It is known that organic compounds that are dissolved in the OSPW are responsible for most toxic effects, but knowledge of the specific chemicals that cause this toxicity, or the associated mechanism(s) of toxicity, is limited. Using a top-down approach, a spreadsheet model has been developed to predict the acute toxicity of the organic fraction of OSPW to early-life

stages of fathead minnow (*Pimephales promelas*). Mixture composition and the concentration of individual mass fractions is characterized by use of linear ion trap (orbitrap) ultrahigh resolution mass spectrometry. Measured octanol- water partition coefficients (log  $K_{ow}$ ) are established by polydimethylsiloxane (PDMS)-coated stir bar sorptive extraction. A narcosis mode of action is assumed and the target-lipid model of Di Toro *et al.*, 2000 is applied for toxicity predictions of individual mass fractions. The toxicity of the whole mixture is predicted assuming concentration addition of the individual mass fractions. The predicted toxicity of the organic fraction of OSPW was compared to the observed toxicity from in-lab 96-hr assays of embryo lethality. Predictions compared well with measured acute toxicity and highlights the usefulness of this spreadsheet model for predicting the acute toxicity of the organic fraction of OSPW to embryos of Fathead minnow. Using a bioassay-effect directed analysis, we have identified fractions of OSPW organics which have acute toxicity. Accuracy of this model to predict the toxicity of acutely toxic fractions of OSPW organics was within 45% of the measured values and within the 95% CI of the measured dose-response relationship.

#### Substitution of hazardous offshore chemicals in UK waters: an evaluation of their use and discharge from 2000 to 2012

M. La Vedrine, Cefas Lowestoft Laboratory / Chemical Assessment Team; D. Sheahan, R. Gioia, B. Rowles, S. Kroeger, C. Phillips, Cefas; M. Kirby, The offshore oil and gas industry will use and discharge large quantities of chemicals into the marine environment during operational activities, with some of those chemicals considered hazardous. Chemical substitution, as part of the environmental regulatory regime, has been advocated as a simple and effective tool to reduce hazardous discharges. In 2007 the UK National Plan was introduced, to prioritise into four groups and subsequently phase out in stages the most hazardous substances used and discharged during offshore oil and gas operations. Level 1 substances categorised for phase out in 2010 were virtually eliminated from discharge between 2006 and 2012 and there was a significant decline in discharge of substances at Level 2 to 4 over the same period. The discharge of substitutable substances had been reduced to less than 5 tonnes at most production installations by 2012. More than 91% of this discharge is contributed by corrosion inhibitor, scale inhibitor, demulsifier and water clarifier formulations. The discharge of corrosion inhibitors accounted for the largest contribution to UK National Plan Level 2 substitutable substance discharges, and they appear to be the type of product with the fewest options found for substitution. This implies that a finite discharge of substances from these groups will continue to require formal justification beyond the target date, as occurred for Level 1 substances after the 2010 target date. The overall figures for substitutable substance discharges from 2006 to 2012 suggest that the introduction of the UK National plan with prioritisation of substances for substitution and ongoing encouragement of operators and, indirectly, suppliers to work towards reduction goals for substitutable substances is resulting in a reduction in discharges and contributing to their ultimate phase out. The next few years will be particularly challenging as the deadline for the phase-out of discharges of substitutable substances included in OSPAR Recommendation, 2006/3 is 1 January 2017 and, in addition, by 2018 all chemical substances used offshore will need to have been registered under REACH. Our work illustrates the benefits of a prioritised strategy for chemical substitution. A continuing dialogue with the regulator, offshore operators and suppliers will be essential to ensure that alternative technical solutions are trialled and options for substitution are investigated at the earliest stage.

### Scales and interactions in community and ecosystem ecotoxicology (PC)

### TUPC01

#### How food web interactions and toxic stress combine to affect biodiversity

D. Kulkarni, Laboratory of Environmental Ecosystem Ecology; C. Melian, Swiss Federal Institute of Aquatic Science and Technology Eawag / Center for Ecology Evolution and Biogeochemistry; F. De Laender, Université de Namur ASBL / Laboratory of Environmental Ecosystem Ecology

Biodiversity is an important indicator of community structure and a predictor of ecosystem functioning. Chemicals have the potential to affect biodiversity of key trophic levels such as primary producers and consumers but if and how these effects propagate in ecosystems through food web interactions (top-down and bottom-up processes) is unknown. We extended a recently developed community model, that considers both intra and interspecific tolerance variability to describe toxic effects on relative species abundances within a larger metacommunity, to multitrophic communities to investigate how toxicity-induced biodiversity effects propagate in food webs. Within the model, a zooplankton community (trophic level 2) interacts with the phytoplankton community (trophic level 1) through grazing. We simulated species abundances at different connectance values and toxicity profiles for an initial population of 50 predators and 50 prey for two toxicants respectively- an insecticide, that affects only the zooplankton community, and a herbicide that only affects the phytoplankton community. We also carried out a literature review for studies dealing with the reciprocal effects of predator and prey diversity on prey and predator diversity respectively using the search terms *predator*, *prey*, *aquatic*,

*diversity* using the ISI web of Science database. A synthesis of observed literature data was compared to model predictions. At lower connectance values, a toxicant-induced reduction in predator diversity led to increased prey diversity while a toxicant-induced reduction in prey diversity led to reduced predator diversity. Effects at higher connectance values were less pronounced compared to those at lower connectance values. Top-down and bottom-up cascading effects of predator and prey diversity have been documented in scientific literature. While a decrease in predator diversity leads to a clear increase in prey diversity, a decrease in prey diversity is shown to have both positive and negative effects. Our model can explain the top-down effects of predator diversity as well as the negative bottom-up effects of prey diversity. We conclude that food web interactions under toxic stress significantly contribute to changes in plankton biodiversity and these changes are more pronounced at low connectance values.

#### TUPC02

##### Effects of intra- and interspecific competition on the sensitivity of *Daphnia magna* populations to the fungicide carbendazim

A. Del Arco, UNIVERSITY OF JAÉN / ANIMAL BIOLOGY PLANT BIOLOGY AND ECOLOGY; P. van den Brink, AlterraWageningen UR / Aquatic Ecology and Water Quality Management Group b Alterra; A. Rico, Wageningen University / Environmental Risk Assessment

The Ecological Risk Assessment (ERA) of pesticides is based on information obtained from single-species toxicity tests in which ecological interactions (i.e., competition, predation) are not taken into account. This poses a challenge for the extrapolation of this data to protect populations under field conditions. It is expected that competition (intra- and interspecific) will result in additional stress, thus resulting in an increase of the sensitivity of aquatic populations to toxicants. In order to test this hypothesis, an experiment with five levels of competition (i.e., control, medium and high intraspecific competition, medium and high interspecific competition) and four carbendazim (i.e., control, low, medium and high exposure concentrations) treatments was set-up. This experiment aimed to assess the effects of carbendazim on the population dynamics of the crustacean *Daphnia magna* under different competition levels. The competition was established based on algal food availability, using different *D. magna* densities for the intraspecific competition, and *Brachionus calyciflorus* as competing species for the interspecific competition. The experiment was performed in glass jars (1.5 L volume) under controlled laboratory conditions, and consisted of a pre-treatment period of 4-days, in which competition was allowed to occur, and a 21-day exposure period. Results of these experiments showed no statistically significant differences owing to combined effects of carbendazim and competition. However, species interactions resulted in noticeable effects when comparing the corresponding *D. magna* EC50 values. Such effect triggered a different response under intraspecific and interspecific competition. While intraspecific competition slightly increased the sensitivity of *D. magna*, as it was expected, interspecific competition seemed to reduce it. The later response was most likely related to an indirect effect explained by the alleviation of the food limitation stress caused by the grazing of *D. magna* over *B. calyciflorus*. These diverse responses point out the complexity of populations responses when ecological interactions are given weight. In conclusion, competition effects are not easy to classify, but experiments suggest that they play an important role in defining population-level effects of pesticides. Hence, more studies are needed to better characterize ecological interactions before they are included in future ERAs.

#### TUPC03

##### Combined effects of temperature and zinc on a microcosm freshwater community

D. Van de Perre, Ghent University Laboratory of Environmental Toxicology and Aquatic Ecology / GhEnToxLab; F. De Laender, Université de Namur ASBL / Laboratory of Environmental Ecosystem Ecology; I. Roessink, Alterra; P.J. van den Brink, Alterra and Wageningen University; C. Janssen, University of Ghent / Laboratory of Environmental Toxicology and Aquatic Ecology GhEnToxLab unit; K.A. De Schampelaere, Ghent University (UGent) / Laboratory for Environmental Toxicology and Aquatic Ecology GhEnToxLab unit

During the last decades the earth's climate has changed rapidly by human activity. Several studies have already investigated the effect of global warming on aquatic communities. However, most studies have so far focused on the effects of single stressors, while in nature multiple stressors are usually present simultaneously. Predicting and understanding the consequences of global warming on aquatic populations and communities are a primary goal of ecotoxicological research. The main objective of this study was to assess the combined effect of temperature and zinc on an aquatic community. An indoor freshwater microcosm experiment was conducted in which temperature (natural conditions: 16-19°C, global warming prospective: 21-24°C) and zinc (control, 75 µg/l & 300 µg/l) were varied in a full 2x3 factorial design. During the experiment general water quality (Total P, dissolved P, NO<sub>3</sub>, NO<sub>2</sub>, NH<sub>4</sub>, DOC, DIC, pH, hardness, BOD<sub>5</sub> and O<sub>2</sub>) and plankton abundance (phytoplankton, protozooplankton and zooplankton) community composition were recorded weekly, starting the day before the start of the treatment. Interactive effects between the different stressors on the endpoints were determined by comparing observed values with values predicted with the independent action model. The significance of the interactions (three-way and two-way) and the main effects were tested by using ANOVA's (three and two-way)

on log-transformed observed data. By evaluating the combined and interactive effects of temperature and zinc on a freshwater microcosm community, it can be concluded that there are significant interactions between the stressors for the different plankton groups. Temperature and zinc are both affecting the primary producers while the zooplankton are mainly affected by zinc. Significant antagonistic interactions between temperature and zinc were observed from 3 weeks of exposure and later for total chlorophyll. Primary producers and the zooplankton community in this study were not more vulnerable to zinc stress at warmer temperatures. However, higher temperatures seem to alter the structural effect zinc has on the community.

#### TUPC04

##### Spatially-explicit individual-based models of competition: impact of stress on resilience

h. haveco, Environmental Risk Assessment Team; A. Focks, Alterra Wageningen University and Research Centre / Ecotoxicology Environmental Risk Assessment Team; F. De Laender, Université de Namur ASBL / Laboratory of Environmental Ecosystem Ecology; M. Trijau, Institut de Radioprotection et de Sûreté Nucléaire; P.J. van den Brink, Alterra and Wageningen University

When competition leads to additional mortality, and the mortality scales with the density of competitors, stability characteristics of individual-based models (IBMs) of competition can be approximated by classical Lotka-Volterra models. From theoretical analyses, it is known that possible outcomes are competitive exclusion, coexistence or bi-stability (dependence on initial conditions). In the Chimera project, we coupled IBMs for *Asellus aquaticus* and *Gammarus pulex*, added competition terms to each, and studied the impact of chronic and pulsed stress on population stability and recovery. We investigated a spatially uniform system, and a system with a spatial gradient or seasonal variation in the background mortality rate of one of the species. We found that in a spatially uniform system, chronic stress could modify the outcome of competition, and shift the balance towards dominance of the insensitive species. With a spatial gradient including a range of values for which bi-stability would be expected, we observed that these local conditions were reflected by local densities only at very low rates of movement. Only then, a relatively clear boundary was observed between areas where either species was dominant, where coexistence occurred, or where bi-stability occurred. At realistic movement rates species tended to be present at locations where they (based on local conditions) were predicted to be outcompeted, causing a lowered competitor density at these locations. Results obtained for uniform systems may explain the observed impact of competition on recovery in experimental systems. For spatial and seasonal systems, model results indicate that the underlying local dominance outcome is not always reflected by local density. Several other typical patterns in the dynamics after a stress pulse were observed. For example, a reduction of the competitor population could lead to a huge increase of the outcompeted species' population size, thus temporarily reversing the trend for this species of being on its way to extinction. Also, in systems with an environmental gradient leading to bi-stability, densities were not likely to return to their exact pre-stress value after a single stress pulse. We catalogued all possible dynamics and outlined the implications for chemical risk assessment. *Acknowledgement* – The Chimera project is financed by the Long Range Initiative of CEFIC ([www.cefic-lri.org](http://www.cefic-lri.org)) (project code: LRI-ECO19)

#### TUPC05

##### Long-term effects of the fungicide pyrimethanil on aquatic primary producers in macrophyte-dominated outdoor mesocosms in two European ecoregions

R. Mueller, Goethe-University, Institute of Occupational, Social and Environmental Medicine / Aquatic Organisms and Ecosystems; C. Shinn, IMAR-Marine and Environmental Research Centre / Laboratoire Evolution et Diversité Biologique; M. Moreira-Santos, University of Coimbra, IMAR-CMA / Department of Life Sciences; R. Ribiero, University of Coimbra

Differences of environmental (including climatic) conditions in specific ecoregions are recently being considered in the European environmental risk assessment of pesticides, although empirical data supporting sound ecoregion-specific ecotoxicological evaluations are scarce. To shed new light on ecotoxicological pesticide effects on aquatic communities across different ecoregions, the model pollutant pyrimethanil (fungicide) was tested in an outdoor mesocosm study with macrophyte-dominated communities in the European "South" (Portugal) and "Centre" (Germany) regulatory zones. Phytoplankton indicators monitored over 12 months indicated a low risk of the fungicide (0.73 or 0.77 mg pyrimethanil L<sup>-1</sup>, single application) for phytoplankton functioning. However, growth of key structural macroalgae and macrophytes were affected by the fungicide and negative effects occurred especially in the Central zone experiment. Effects of pyrimethanil on primary producers in macrophyte-dominated mesocosm communities were not detected earlier than approximately nine months post single pyrimethanil application. The presence or absence of such extremely long-lasting pyrimethanil effects depends on the species, competitive situation, and ecoregion-specific physico-chemical environment. The present findings suggest that a better understanding of both direct and indirect effects of fungicide pollution on aquatic flora in two European ecoregions helps to consolidate environmental risk assessment of pesticides in specific regulatory zones.

## Predicting effects of wastewater stressors on river ecosystems

A. Franco, Unilever / Safety and Environmental Assurance Centre; N. Furmanski, Unilever / Direction du Développement et de la Prospective  
Current regulatory practice for chemical risk assessment lacks ecological realism and does not provide sufficient information on the potential ecological impact caused by chemical exposure. This is particularly problematic in heavily stressed river ecosystems receiving direct discharges of untreated wastewater. Ecological effect models have been proposed to better extrapolate responses observed on individuals in laboratory ecotoxicological tests to effects on populations and communities in complex, multistressed environments. However, the application of ecological models to improve the risk assessment of down-the-drain chemicals such as ingredients of home and personal care products remains largely unexplored. Here we present case studies using two ecological models of different complexity to predict changes in community composition and dynamics caused by wastewater stressors: The first case study presented is a conceptual model based on species sensitivity distribution applied to the South Elkhorn Creek (Kentucky, US) to predict changes in community composition downstream of wastewater outfalls. The second model tested is the process-based, integrated fate and effect model AQUATOX, applied to the Rivers Thames (UK) and Po (Italy). The objective of the work was to review available biomonitoring data needed to develop ecological scenarios and models and to present the learning form the case studies and discuss research priorities. Different aspects of ecological realism such as the consideration of multiple wastewater stressors or the consequence of food web interactions on community dynamics are best addressed by fit-for-purpose models. Both approaches presented illustrated that modelling ecological communities require detailed biomonitoring data for parameterisation and testing. Such datasets are scarce for river ecosystems but are critical to better understanding and defining the ecological status and traits (or species) that are most sensitive to chemical stressors in different ecological scenarios. Given the complexity of ecosystem level interactions and the resource limitations to develop and test modelling approaches, ecological scenarios at higher risk need to be prioritised for further analysis based on both exposure and ecological considerations.

## Rational design of chemicals and pharmaceuticals and other input prevention measures towards sustainable technological development (PC)

### TUPC07

#### How environmentally friendly are cholinium based ILs?

A.M. Gonçalves, Biology; J. Santos, University of Porto, CIIMAR & ICBAS, Laboratory of Ecotoxicology; J. Pereira, University of Aveiro & CESAM / Department of Biology; F.L. Silva, S. Ventura, J.L. Coutinho, University of Aveiro / Chemistry; F. Gonçalves, University of Aveiro CESAM / Department of Biology

Ionic liquids (ILs) are salts with low melting points and liquid at or close to room temperature. Their cation group designates the IL family and both the cation and the anion can be functionalized depending on the intended properties. Their rational (environmentally concerned) design can benefit from information retrieved by the ecotoxicological assessment of the chemical structure functionalization. Nowadays, there is an increasing number of cholinium-based ILs being synthesized, but this family is not well characterized yet. This interest is based on the fact that cholinium is an essential nutrient, so these ILs are believed to be solvents with lower environmental hazardous potential, with a multitude of biotechnological applications. In order to properly evaluate the ecotoxicity of this IL family, a range of anion hydrophobicities were studied using ten compounds with a cholinium core and other selected structural features. The ecotoxicological effects of these chemicals on four standard aquatic species (*Vibrio fischeri*, *Raphidocelis subcapitata*, *Lemna minor* and *Daphnia magna*) were recorded to evaluate whether the trends in structure-activity (ecotoxicity) relationships depend on the focused biological model. ILs with shorter alkyl side chains were less toxic to organisms than the ones with longer chains. Also, in general, the introduction of hydroxyl groups promotes a higher toxicity of the ILs for the organisms. The introduction of a phosphate group does not seem to increase toxicity. The analysis of the effect of the aromatic character of these compounds showed distinct results. The introduction of a phenolic group turned this compound more toxic. Still, these trends seem dependent on the focused biological model: for example, the aromatic nature of [BzChol]Cl makes it much less toxic than the non-aromatic version [Chol]Cl for *V. fischeri* and *R. subcapitata*, this tendency suffering an inversion for *L. minor* and *D. magna*. The differences observed in the ecotoxicity between organisms may be explained considering the distinct uptake pathways ruling ILs toxicity. Still, the EC<sub>50</sub> values found for the ten cholinium compounds are lower than those recorded for some organic solvents widely used, namely dichloromethane and ethyl acetate. This suggests that the general assumption that cholinium-based ILs are a more environmentally-friendly alternative to common organic solvents can be challenged.

### TUPC08

#### Atom Economy, Catalysis and Green Toxicology: Tools for Sustainable Chemistry and Drug Discovery

N. Gathergood, Dublin City University / School of Chemical Sciences  
Sustainable chemistry research projects combine three fields of green chemistry; ionic liquids, eco(toxicity) assessment and catalysis. One study is directed towards ionic liquids which can also catalyse reactions. This overlap between organocatalysis and ionic liquid research enables us to design low toxicity and potentially biodegradable catalysts based on the extensive biological screening data of ionic liquids. Assessment of the performance of a new catalyst, in tandem with the (eco)toxicity screening and biodegradation testing allows the chemist to develop greener synthetic methods.<sup>1-3</sup> We have designed a library of aprotic ionic liquids which can act as Brønsted acid catalysts with low antibacterial and antifungal activity. Toxicity evaluation of all the ionic liquids prepared was performed to establish the influence of ester or amide groups in the cation. Antifungal and antibacterial toxicity results show that the ionic liquids did not inhibit the growth of any organism screened at concentrations of 2.0 mM. Biodegradation of the novel ionic liquids was also investigated in “CO<sub>2</sub> Headspace” test (ISO 14593). Our latest work which includes green chemistry metrics feedback, investigates the effect of substitution on the imidazolium ring on biodegradation, toxicity and activity of the catalyst.<sup>2,3</sup> This enables our team to recommend the ‘greenest’ catalyst of our series for further applications. The second part of the talk will introduce the concept that drug discovery can be linked to the search for novel sustainable catalyst scaffolds. **References** 1) Gore, R. G.; Truong, T.-K.-T.; Pour, M.; Myles, L.; Connon, S. J. and Gathergood, N. *Green Chem.*, (2013), 15 (10), 2727-2739. 2) Myles, L.; Gore, R. G.; Gathergood, N. and Connon, S. J. *Green Chem.*, (2013), 15 (10), 2740-2746. 3) Gore, R. G.; Myles, L.; Spulak, M.; Beadham, I.; Garcia, T. M.; Connon, S. J. and Gathergood, N. *Green Chem.*, (2013), 15 (10), 2747-2760.

### TUPC09

#### The effect of aromatic groups on the antimicrobial toxicity of ionic liquids derived from phenylalanine and mandelic acid

H. Prydderch, Dublin City University; A.E. Jordan, Chemical Sciences; S. Ventura, University of Aveiro / Chemistry; M. Gurbisz, M. Ghavre, Dublin City University; F.C. Ferreira, São Paulo State University UNESP; F. Gonçalves, University of Aveiro CESAM / Department of Biology; I. Beadham, B. Quilty, Dublin City University; J.L. Coutinho, University of Aveiro / Chemistry; N. Gathergood, Dublin City University / School of Chemical Sciences; D. Coleman, Dublin City University; M. Spulak, Charles University / Centre for New Antivirals and Antineoplastics, Department of Inorganic and Organic Chemistry, Faculty of Pharmacy; M. Garcia, Institute of Advanced Chemistry of Catalonia

Ionic liquids (ILs) are often described as ‘green solvents’; mainly due to their very low vapour pressure. However, assessment of their environmental impact is also a requirement. ILs must not persist in the environment and should be non-toxic or of limited toxicity to the environment. This is a challenging goal for IL research today. The work of the Gathergood research group is aimed towards the synthesis and analysis of biodegradable, low toxicity ILs and their applications. The Gathergood group has proposed that using renewable resources to form ILs could improve the eco-toxicity of the compounds. Thus, work has been carried out on the synthesis of ILs with a bio-derived anion, namely mandelic acid and the amino acid phenylalanine.<sup>1,2</sup> A broad series of ILs using these two bio-renewable resources as chiral scaffolds has been synthesised and their antimicrobial toxicity evaluated. ILs from phenylalanine with various headgroups and aromatic substituents have been synthesised. Modification of the headgroups on the phenylalanine scaffold has allowed for toxicity studies to be carried out on the effect of aromatic and non-aromatic headgroups. A study focusing on the imidazolium headgroup showed that imidazolium ILs containing phenylalanine were non-toxic (IC<sub>95</sub> > 2 mM) to the twelve fungi strains and eight bacteria strains they were screened against.<sup>2</sup> Dipeptide amino acid examples were also examined in this study and were also found to have low toxicity. A series of eight ILs from mandelic acid with imidazolium and pyridinium headgroups were synthesised to allow for the investigation of toxicity on modifying the heterocycle, aromatic ring substitution, ester group, and proximity of cation to aromatic ring.<sup>1</sup> Two pyridinium ILs showed low toxicity to all bacteria strains and freshwater green algae screened against. All eight pyridinium and imidazolium ILs showed low toxicity to Gram-positive and Gram-negative bacteria strains tested against, with a significant range in IC<sub>50</sub> values. However they were 10<sup>3</sup>–10<sup>7</sup> higher (less toxic) than other C14–C18 ILs previously reported. [1] S. P. M. Ventura, M. Gurbisz, M. Ghavre, F.M. M. Ferreira, F. Gonçalves, I. Beadham, B. Quilty, J. A. P. Coutinho, and N. Gathergood, *ACS Sustainable Chemistry & Engineering*, 2013, 4, 393 [2] D. Coleman, M. Špulák, M. T. Garcia and N. ### TUPC10

#### In silico QSAR prediction of EC50 values for selected short aliphatic protic ionic liquids

B. Peric, Faculty of Pharmacy, University of Barcelona / Soil Science Unit; J. Sierra, Universitat Rovira i Virgili / Soil Science Unit; E. Martí, Universitat de Barcelona / Productes Naturals Biologia Vegetal i Edafologia; R. Cruañas, M. Garau, Universitat de Barcelona  
Ionic liquids (ILs) are considered as a group of very promising compounds due to their excellent properties (non-volatility, high thermal stability and very good and versatile solvating capacity). The ILs have a good prospect of replacing the

traditional organic solvents in vast variety of applications. The number of combinations of cations and anions forming ionic liquids (ILs) is practically infinite and they can be custom designed in order to suite the desired application. But the complete information on their environmental impact is not available. It is clearly not feasible to analyze the toxicity of so many compounds. The application of *in silico* methods such as QSAR could speed up the process of (eco)toxicological evaluation and predict the potential toxicity of ILs before they are considered for commercialization. The QSAR modelling can allow reliable prediction of toxicity, avoiding unnecessary animal experiments, which is also encouraged by ECHA and REACH. In this study, a group contribution QSAR model was used in order to predict the (eco)toxicity of eight protic ILs belonging to a new short aliphatic family which have not been previously experimentally analyzed in five (eco)toxicity tests (Microtox<sup>®</sup>, *Pseudokirchneriella subcapitata* and *Lemna minor* growth inhibition test, and Acetylcholinesterase inhibition and Cell viability assay with IPC-81 cells). The predicted toxicities confirmed the previous findings on the new family of protic ILs, and these eight representatives also showed low or no toxicity. The only toxic effect can be seen towards *Lemna minor* in case of two ILs which have EC50-1, and according to the Globally Harmonized System of Classification and Labelling of Chemicals can be classified as harmful for the aquatic environment (category Acute 3). Additionally, a QSAR prediction of the EC50 values for other ILs was performed and compared with the experimentally determined EC50 and high correlation coefficients were obtained, thus confirming the accuracy of the model. The *in silico* QSAR model applied in this study could allow the selection of potentially less toxic ILs amongst the existing ones, but it can also be very helpful in directing the synthesis efforts towards developing new “greener” ILs, respectful with the environment.

#### TUPC11

##### Metabolite analysis of a series of novel L-Phenylalanine derived Ionic Liquids using a modified Closed Bottle Test protocol and high resolution Orbi-trap MS

A. Haiss, Leuphana University Lüneburg; J. Westphal, Leuphana University Lüneburg / Technology and Management; A.E. Jordan, Chemical Sciences; N. Gathergood, Dublin City University / School of Chemical Sciences; K. Kuemmerer, Leuphana University Lüneburg / Institute of Sustainable and Environmental Chemistry  
Ionic Liquids (ILs) are increasingly seen as an important building block of green chemistry over the past decade because of their specific properties e.g. as solvents such as the potential for high recyclability, low-volatility, low-flammability, low-toxicity, and the potential for synthesis from renewable resources. New applications are anticipated for ILs that may result the introduction of ILs into the aquatic environment. Therefore, another desirable property to be fulfilled by green and sustainable ILs is fast and full mineralisation after they are introduced into the aquatic environment. However, early generations of ILs have shown to be recalcitrant to biodegradation, calling for the need to examine ILs for biodegradability. Currently, biodegradation can be measured by a number of standardized test methods. These tests do not reveal any detailed information on chemical processes and chemical species involved in biodegradation. A deeper insight into the course of biodegradation of ILs can be gained by employing high resolution Orbi trap MS. This will allow for the rational design of ILs according to the “Benign by Design” concept. The biodegradation screening of a series of L-Phenylalanine derived ILs was performed (28 and 42 days was performed). The fragments detected were then synthesised from first principles and their MS/MS was compared to those extracted from the CBT vessel to complete the structural elucidation. Only halide ILs have been screened so as to remove the variability of biodegradable anions. None of the IL cations tested reached the ready biodegradability threshold with 28 days. One did after 42 days indicating the adaptation of microorganisms to the test compound. TPs have successfully been identified by high resolution MS. Not all ILs tested gave a persistent fragment. The identification of recalcitrant TPs is gave new insights thus demonstrating the added value of the approach. The results are of paramount importance for designing next generation ILs as they present a platform upon which readily/ultimately biodegradable ILs can be designed from. Avoiding persistent cation/anion fragments as determined by metabolite studies and employing the identified readily biodegradable building blocks presents a innovation in IL design.

## Mercury Pollution: Chemistry, Remediation and Policy (PC)

#### TUPC13

##### Mercury Regulation Issues in Armenia

A. Aleksandryan, Hazardous Substances & Waste Policy Division / Head of Division

The Republic of Armenia signed Minamata Convention on Mercury that is the main strategy document for regulation of mercury, its compounds with the aim to reduce or, where possible, eliminate mercury use in industrial sectors and supposes to systematically reduce emissions and releases to land and water, and phase out the use of mercury where alternatives exist, as well as recycle wastes. At present, in Armenia mercury is used in and emitted from industrial applications (lighting equipment, chlorine production, cement production, mining, synthetic rubber production, and pesticides) and medical appliances (dental amalgam filling and

thermometers). The import and/or export of chemicals and pesticides are regulated by the Rotterdam Convention. The List of chemicals and pesticides regulated by Rotterdam Convention and banned in the Republic of Armenia involves compounds of mercury, including: inorganic mercury compounds, compounds of alkyl mercury, as well as alkyloxyalkyl and arylated compounds of mercury, which are prohibited by the Governmental Decision. Another important legislative document is the List of the Republic of Armenia hazardous waste that was approved by the Governmental Decision. This List includes (i) wastes containing mercury, mercury compounds as a component or pollutant, (ii) scrap (wastes), electrical equipment or electro-technical nodes, involving galvanic elements, batteries, mercury switches, glass of cathode ray tubes and other types of glass with the active covering or polluted by cadmium, mercury, lead, polychlorinated biphenyls at the concentration level from 50 mg/kg and above, (iii) worked-out mercury lamps and luminescent tubes. The List of the Republic of Armenia banned hazardous waste, among others, includes wastes containing mercury, mercury compounds as a component or pollutant; the List was approved by the Governmental Decision. In the Republic of Armenia the List of wastes banned for import was also approved. All the Decisions and by-laws are of importance for the sound management of mercury, mercury compounds, as well as mercury containing products and wastes.

#### TUPC14

##### Bioavailability of mercury: benthic organisms vs. passive sampling

L. Marziali, IRSA-CNR (Brugherio); M. Camusso, Italian National Research Council Water Research Institute CNRIRSA; S. Pascariello, A. Drago, IRSACNR Brugherio; F. Rosignoli, Italian National Research Council Water Research Institute CNRIRSA; G. Tartari, IRSACNR Brugherio / UOS Brugherio; A. Marchetto, CNR ISE; L. Guzzella, Italian National Research Council Water Research Institute CNRIRSA

Mercury bioavailability was assessed in the Toce river (North Italy), were residual contamination deriving from the activity of a chlor-alkali plant is present in sediments (values up to 1 mg kg<sup>-1</sup> d.w.). Six stations were chosen: 2 upstream and 4 downstream the industrial plant. Different approaches were used: 1) bioaccumulation in native benthic invertebrates belonging to different taxonomic/functional groups (Crustacea Gammaridae, Oligochaeta, Insecta Diptera Tipulidae, Tabanidae and Limoniidae, Ephemeroptera *Baetis* and *Ecdyonurus*, Plecoptera, Trichoptera); 2) bioaccumulation in *Chironomus riparius* (Diptera Chironomidae) exposed to the sediments in standardized conditions; 3) labile mercury measured by deployment of Diffusive Gradients in Thin Films Spheron-Thiol-agarose passive samplers (DGT) both in the lab and on-site. Results showed that collectors and shredders as well as predators exhibited higher Hg concentrations that grazers, confirming that exposure is mainly due to the ingestion of contaminated food (sediments or preys). By comparison, DGT samplers proved to be effective tools in on-site exposure for assessing Hg bioavailability to benthic organisms. As a confirmation, *C. riparius* and DGT samplers showed similar response in the lab exposure. The different approaches will be considered for the ecological risk assessment of the riverine ecosystem.

#### TUPC15

##### Mercury levels in forest and grassland soils in the surrounding area of a cement plant in NW Spain

L. Cutillas-Barreiro, University of Vigo; P.P. Rodríguez, Universidade de Vigo / Plant Biology and Soil Science; A. Gómez-Armesto, University of Vigo / Plant Biology and Soil Science; J. Nóvoa-Muñoz, M. Arias-Estévez, University of Vigo; E. Álvarez-Rodríguez, M. Fernández-Sanjurjo, A. Núñez-Delgado, University of Santiago de Compostela

Cement plants have increased its contribution to emissions of heavy metals into the atmosphere due to the presence of the pollutant in cement raw materials (limestone and clay), as well as to the burning of fossil fuels (coal, fuel, gas). Although control systems aid to minimize pollution risks, cement facilities emit a significant burden of Hg, a volatile heavy metal with high toxicity potential. As a result, Hg is frequently found in soils of the surrounding areas, where it may cause relevant environmental problems. In this study, soil samples were taken in forest and grassland soils, at intervals of 10 m, concentrations were determined using an Hg auto-analyzer. Forest soils showed Hg<sub>T</sub> concentrations between 41 and 117 µg kg<sup>-1</sup>, being higher in organic than in mineral horizons, thus indicating the prevalence of atmospheric sources. Grassland soils exhibited Hg<sub>T</sub> levels (13-65 µg kg<sup>-1</sup>) that were lower than that in forest soils, being similar at different depths. Hg<sub>T</sub> contents in rock samples were around 5 µg kg<sup>-1</sup>, indicating the scarce relevance of the lithological source. These results are in accordance with an increased capacity to filter atmospheric Hg corresponding to forest vegetation, contrasting with that of herbaceous vegetation in grassland soils. On the other hand, the distance to the cement facility did not affect Hg<sub>T</sub> concentrations, whereas orientation had a clear influence, with NE soils showing higher Hg values than those located at SW. Although Hg<sub>T</sub> concentrations were lower than that considered critical load for soils (130 µg kg<sup>-1</sup>), the dense river conformation in the watershed corresponding to the study area could be an ideal environment for the transformation of Hg to more toxic forms (methyl-Hg). In addition, grazing and overall consumption of vegetation in grassland soils could facilitate the transfer of Hg into the food chain. Globally, this preliminary study indicates the need to further investigate the implications of the accumulation of Hg in soils surrounding the cement facility under consideration.

## TUPC16

### Various bacterial guilds contribute to methylmercury formation in sediments contaminated by sewage treatment plant discharges

A.G. G. Bravo, Department of Ecology and Genetics, Limnology / Department of Ecology and Genetics Limnology; J. Zopfi, University of Basel / Environmental Geosciences; S. Bertilsson, Uppsala University / Department of Ecology and Genetics Limnology; S. Bouchet, Université de Pau et des Pays de l'Adour / LCABIEIPREM UMR CNRS; D. Amouroux, LCABIE IPREM / UMR CNRS; J. Dominik, Istituto di Scienze Marine - Consiglio Nazionale delle Ricerche; C. Cosio, Geneva University / Institute Forel Earth and Environmental Sciences

The methylation of inorganic-Hg (IHg) to methylmercury (MeHg), which is bio-accumulated and biomagnified in food webs, is a major concern because MeHg can affect human health. The formation of MeHg, (i.e. Hg methylation) takes place under suboxic to anoxic conditions and it is genetically mediated by sulfate-reducing bacteria (SRB), iron-reducing bacteria (FeRB), methanogens and/or firmicutes. Previous studies demonstrated a concomitant release of Hg, iron and organic matter by many sewage treatment plant (STP) discharges. The aim of this study was thus to assess the impact of the STP's discharges on Hg methylation in sediments, with a particular attention to the role of iron and different bacterial guilds on Hg methylation. We combined a geochemical and microbiological characterization with Hg speciation and sediment amendment experiments to evaluate the impact of STP's effluents on MeHg production. We collected sediment material at two stations in the Vidy Bay that differ in their degree of exposure to STP emissions. In all samples proteobacteria was the dominant phylum ( $28.6 \pm 1.6\%$  of total OTUs), followed by *Bacteroidetes* ( $16.5 \pm 2.4\%$ ), and *Chloroflexi* ( $11 \pm 2.7\%$ ). Functional genes' analysis revealed a high abundance of FeRB, SRB and methanogens. The *hgcA<sub>tot</sub>* (present in all the Hg methylating bacteria) was highly variable with no obvious trend, while the *hgcA<sub>Geo</sub>* (only present in Hg methylating *Geobacteraceae*) was high and stable in all the samples. In the sediment amendment experiments, addition of sulfate always led to lower methylation yields ( $1.5 \pm 0.3\%$ ) compared to  $2.3 \pm 0.2\%$  in the control despite the observed higher sulfate reduction rate. Hg methylation was thus enhanced while SRB were inhibited and FeRB were more active (compared to control). At first sight, this suggests that FeRB are important methylators. However, Hg methylation in incubations with added iron were similar or slightly higher ( $2.7 \pm 0.3\%$ ) than in the control, while the iron reduction rates were highest and sulfate reduction was almost shut down. Thus the results of the sediment amendment experiments and the sediment microbiological characterization indicated that besides FeRB, other microorganisms may significantly contribute to MeHg formation in sediments impacted by STP discharges.

## TUPC17

### An ecotoxicological assessment of heavily mercury-contaminated soils from Almadén (Spain) revealed not acute toxicity

J. Borí, Universitat Politècnica de Catalunya (UPC) / Centre for Research and Innovation in Toxicology CRIT; A. Arnaiz, Universitat Politècnica de Catalunya UPC; B. Valles, Universitat Politècnica de Catalunya UPC / Centre for Research and Innovation in Toxicology CRIT; J. Sanchez-Hernandez, Universidad de Castilla-La Mancha; M. Riva, Universitat Politècnica de Catalunya UPC

Ecosystems in the mining district of Almadén (Ciudad Real, Spain) are one of the most mercury contaminated worldwide, but little is known about the toxic effects on biota. In the present study, potential toxicity of soils collected from Almadén was examined through different terrestrial and aquatic ecotoxicity tests. Soil toxicity testing involved the use of *Eisenia fetida*, *Folsomia candida* and multiple plant species as test organisms, and covered a wide range of long-term and short-term lethal and sublethal endpoints. Aquatic tests used leachates from the test soils to assess the growth inhibition of *Pseudokirchneriella subcapitata* and the lethality on *Daphnia magna*. Results showed that, despite the extremely high concentrations of mercury in some soils, this metal did not cause a significant change in most ecotoxicity tests. This lack of response may be due to mercury speciation in this abandoned mining area. It has been long documented that Hg in Almadén's soils is mainly found as cinnabar, and it shows a low bioavailability. Nevertheless, there was a significant response in both *Folsomia candida* avoidance behaviour test and *Pseudokirchneriella subcapitata* growth inhibition test with Hg-contaminated soils compared to control (mercury-free) soils, which suggested these sublethal tests as the most appropriate choice in further biomonitoring programs of Hg-contaminated soils.

## TUPC18

### Mercury distribution in two soils from Almadén sites under the influence of past intensive mining activities

M. Sierra, J. Rodríguez-Alonso, N. ARÉVALO, CIEMAT / Environmental; R. Millán, CIEMAT / Department of Environment

The main objective of this work is to study the distribution of Hg in two soils from Almadén areas which had mining activities in the past. These two enclosed scenarios are an abandoned Hg metallurgical site where cinnabar (HgS) was roasted by furnaces to obtain primary Hg in the 18th century and plot where there are remains of an old mining dump and an abandoned mine entrance active from 15th to 18th centuries. To study the mercury distribution in these soils an specific six-step sequential extraction procedure developed by Sánchez et al. (2005) was applied. The results show that mercury is mainly found associated to the most resistant

forms and, nevertheless, the lowest Hg concentrations are found in more labile forms (water-soluble phases, exchangeable fraction, carbonates and amorphous oxyhydroxides). Anyway, despite of the low percentages of Hg associated to labile forms, the actual contents of easily available Hg are important since Hg contents in the study original soils where mining activities were carried out, are high (from 5 to 40000 mg kg<sup>-1</sup>). Therefore, the actual content besides percentage should be considered in order to assess potential decontamination strategies and future safe land uses for minimizing human and environmental risks. Keywords: mercury, SEP, mine area, Almadén

### Co-adsorption of propranolol and copper (II) on soils

R. SMITH, ChampagneArdenne; S. Sayen, University of Reims Champagne-Ardenne; E. Guillon, Université de Reims Champagne Ardenne / Institut de Chimie Moléculaire de Reims ICMR UMR CNRS Groupe Chimie de Coordination

Over the last decades, the discharge of pharmaceuticals in the environment has become an issue of great concern and pharmaceutical compounds have been identified as emerging environmental contaminants. The main sources of pharmaceuticals are the wastewater treatment plants (WWTP) effluents and soil amendments (sewage sludge, manure, slurry,...). Beta-blockers are among the most widely used pharmaceuticals whose concentrations in different environmental compartments vary from ng.L<sup>-1</sup> to µg.L<sup>-1</sup>. Moreover, their presence can produce damaging effects on ecosystems as well as on human health. It is therefore fundamental to study their fate in the environment. Predicting the transport and fate of beta-blockers in the environment especially requires to understand their adsorption onto soils and sediments. In this study, we investigated the adsorption of one beta-blocker, propranolol (Scheme 1), in three different soils as function of contact time, propranolol concentration and pH. Moreover, given such molecules can interact with heavy metals present in the environment, we also report the influence of the copper presence on propranolol retention on soils. The results show that propranolol adsorption is rapid and that the adsorbed amounts depend on the soil physico chemical properties. The adsorption coefficients K<sub>d</sub> were determined and the obtained values were better correlated to the cationic exchange capacity (CEC) than the organic matter (OM) content. Surprisingly, no influence of copper was observed on propranolol adsorption in spite of the formation of a Cu(II)-propranolol complex previously evidenced. Thus, propranolol mobility in the environment is not influenced by the presence of copper. **Keywords:** adsorption, metal, beta-blocker, soil, pharmaceutical

## TUPC20

### Two methods to reduce cadmium in wheat crops

T.H. Landberg, Stockholm University / Department of Ecological Environmental and Plant Sciences; M. Greger, Stockholm University / Department of Ecology Environment and Plant science

Cadmium (Cd) is a highly toxic and hazardous element. In Sweden 43 % of the daily Cd-intake originates from wheat, due to high Cd accumulation in wheat grains and a large consumption of wheat products. To decrease the Cd intake the Cd uptake by wheat plant from soil and the transport of Cd to the grains should be prevented. The aim was to test two methods to decrease Cd concentration in wheat grain in field cultures: 1) phytoextraction (use of plants to remove Cd from the soil) and 2) silicon (Si) supplementation, where Si make Cd less available for plants and the transport from root to shoot of Cd is prevented by Si. Phytoextraction was performed by the use of *Salix* (*Salix viminalis*) cultivated in clayey and sandy soil, respectively, for 1-4 years prior to cultivation of wheat (spring and winter wheat; *Triticum aestivum*). Wheat was then cultivated several years after the soil has been remediated. Silicon was added (0-500 kg/ha) one month after sowing in spring wheat culture. Results showed that already after one year of phytoextraction the soil Cd concentration decreased with 8%. After 4 years phytoextraction the Cd concentration decreased with up to 25 % and that of wheat grains with up to 32%. When Si was added, the largest decrease of Cd in wheat grains was 10%, found at the highest Si addition. It was found that at for a Si effect more than 160 kg/ha of Si has to be added.

## TUPC21

### Effect-direct analysis of AhR-active organic compounds in industrial soils contaminated by creosote

M. Delafoulhouze, LPTC EPOC UMR5805 / LPTC EPOC UMR; S. Ait-Aissa, INERIS / Ecotoxicology Unit; H. Budzinski, University of Bordeaux / UMR EPOC Equipe LPTC

**Contaminations of industrial soils are generally difficult to assess due to the presence of complex mixture of many pollutants. The identification of contaminants which are responsible for biological effects is an important issue for the remediation of industrial sites and soils. Effect-directed analysis (EDA) is a quite new approach which combines bioassays, chemical fractionation and chemical analysis to identify pollutants having biological effects. The use of EDA to identify contaminants in industrial soils focuses on novel compounds**

that would allow to adapt soil remediation methodology based on identified molecules and to find new relevant molecules to track for soil risk assessment. The methodology should be fast, cheap and repeatable in order to interest the industrials. Here, EDA has been developed with an extraction of pollutants by pressured liquid extraction, and fractionation by normal phase HPLC. It was been applied on an industrial site contaminated by creosote, a complex mixture containing several hundreds of molecules even if PAHs present 80% of its mass. The results show that this soil is contaminated by molecules able to activate the aryl hydrocarbon receptor. The fractionation shows a good repeatability and a separation of the AhR activity among different fractions. AhR activity is distributed between fractions 7 and 16 with a more important activity for fraction 7 and 8. With this fractionation methodology, PAHs are eluted between fractions 4 and 8. The activities of these fractions are responsible of 66% of total AhR activity. By using toxic equivalent factors (TEF) based on Benzo(a)pyrene, the 16 PAHs of US-EPA explain 4% and 70% of AhR activity in F7 and F8 respectively. However, majority of AhR activity is due to another molecules that 16 PAHs of US-EPA and which are not quantified for soil risk assessment. Furthermore, majority of these AhR activators are eluted with a more polar fractions involving that molecules are more hydrophilic and possibly more mobile. GC-Q/ToF analyses are under progress to identified molecules present in active fractions.

##### Impact of mining activities on ecosystems: studies under semiarid Mediterranean climate in SE Spain

J. Álvarez-Rogel, H.M. Conesa, I.M. Párraga-Aguado, M. Tercero, Escuela Técnica Superior de Ingeniería Agronómica Universidad Politécnica de Cartagena / Ciencia y Tecnología Agraria; M. González-Alcaraz, Faculty of Earth and Life Sciences, VU University / Ecological Science  
This presentation is an overview of the results obtained in a number of recent studies carried out in the old mining area of La Unión-Sierra de Cartagena and in the polluted wetlands of the Mar Menor lagoon (SE Spain). The mine soils, and the soils and marine bottoms affected by them, showed a wide range of pH values, from acidic (pH 3-4) to neutral-basic (pH 7-8). The whole of the results indicated extremely high concentrations of metal(l)oids in the tailings, the surrounding areas and the affected wetlands (in mg kg<sup>-1</sup>): As (~100 to ~2000), Cd (~30 to ~120), Cu (~50 to ~150), Mn (~4000 to ~13000), Pb (~1500 to ~20000) and Zn (~4000 to ~31000). The concentrations of extractable metal(l)oids were considerably lower and depended on the chemical reagent used (deionised water, EDTA and CaCl<sub>2</sub>). Metal accumulation was found in inland and wetland plants and in marine molluscs. In the mine tailings, after the pioneer plants started to colonise small patches of favourable edaphic conditions, a facilitation process favoured that other species were able to grow. Late successional stages were found as part of the so called 'fertility islands', showing that natural succession might be successful. In the most extremely saline environments of the polluted wetlands, the disturbance due to mine wastes was not determinant to influence vegetation composition, but it was important in degraded dune systems and dry watercourses. Greenhouse experiments showed that in the absence of flooding conditions, liming decreased the soluble metal concentrations and favoured the growth of *Sarcocornia fruticosa* (a halophyte species), and enhanced the capacity of this species to phyto-stabilise metals in the roots. When neutral wastes were subjected to alternating flooding-drying conditions, liming decreased the concentrations of Mn, Zn and Cd in pore water of bare soils, but not Cu and Pb. When liming and plants were combined, *S. fruticosa* counteracted the effect of the amendment, strongly increasing the concentration of metals in pore water. In acidic wastes (pH ~3.5-4.0), liming decreased the soluble Zn, Cu and Pb concentrations, but increased soluble Mn and Cd, especially in the treatment with liming and *S. fruticosa*. These studies revealed that the phytomangement of areas affected by mine wastes must consider the specific characteristics of each case and that the use of non-specific remediation measures is strongly advised against.

#### TUPC23

##### Activated carbons prepared from plum, apricot and cherry kernels: Influence of operational parameters and elemental composition on the yield of product

S. Pap, University of Novi Sad Faculty of Technical Sciences; J. Radonic, Faculty of Technical Sciences; M. Brboric, M.V. Miloradov, Z. Djukic, M.S. Turk, University of Novi Sad / Faculty of Technical Sciences  
The effective removal of heavy metals from aqueous wastes is among the most important issues for many industrialized countries. Activated carbon, an adsorbent with large porous surface area, controllable pore structure and thermo-stability is recognized as the most efficient and promising fundamental approach in the wastewater treatment processes (removing of dyes, heavy metals and polyaromatic hydrocarbons). Different kinds of agricultural residues could be utilized and the production of activated carbons for the tertiary treatment of industrial wastewaters would be achieved at a reasonable cost. The use of alternative activated carbon derived from biomass, an agricultural waste material, has been investigated as a replacement for the current expensive methods of removing heavy metals from wastewater. Plum, apricot and cherry kernels, a low-cost biomass residue, were used to prepare activated carbon by thermochemical activation with phosphoric (H<sub>3</sub>PO<sub>4</sub>) and sulphuric (H<sub>2</sub>SO<sub>4</sub>) acid as the activating agents at 400°C and 500°C for 2 h. In the study, various parameters such as the impregnation type, activation

temperature and elemental composition of kernels were evaluated to establish the yield of product. It was concluded that the operational parameters and composition of raw materials have significant influence, in the range of 75% to 40%, on the yield of the synthesized activated carbons. **Acknowledgement:** This research has been financially supported by Ministry of Education, Science and Technological Development, Republic of Serbia (III46009).

#### TUPC24

##### Toxicity assessment of soils in a recovered area affected by a mining spill

F.M. Peinado, A. Romero Freire, University of Granada / edafologia y química agrícola; M. SIERRA ARAGON, E. FERNANDEZ ONDONO, University of Granada / Soil Science Department; F.J. Martínez Garzón, University of Granada / edafologia y química agrícola; I. ORTIZ BERNAD, University of Granada / Soil Science Department; O. Kodirov, Academy of Sciences Uzbekistan / Institute of Geology and Geophysics

In 1998 a breach in the Aznalcollar pyrite mine (Sevilla, Spain) spilled around 4.5 x 10<sup>6</sup> m<sup>3</sup> of acidic waters and toxic tailings containing high concentrations of zinc (Zn), copper (Cu), cadmium (Cd), arsenic (As), lead (Pb), and thallium (Tl) into the Agrio and Guadimar river basins. One of the most important soil-remediation programmes in Europe was applied to restore the affected area, concluding with the establishment of the Guadimar Green Corridor. Although the remediation measures gradually decreased the concentration of pollutants in the affected soils, an irregular distribution pattern of contamination in the affected soils was easily discernible, with highly polluted spots alternating with other much less polluted areas. Fifteen years after the accident, most of the affected soils are recovered, although highly polluted spots of soils with variable area (from 1 to 200 m<sup>2</sup>) are easily distinguished in the landscape because no vegetation has developed, representing a major source of pollution that should be monitored. The aim of the present work is to assess the residual contamination and potential toxicity of the unrecovered soils affected by the mine spill 15 years after the accident by the use of toxicity bioassays. The residual pollution is distinguished in the field because no vegetation has developed. The analytical characterization of the area indicate that the unrecovered areas have acidic pH, high concentrations of total Pb and As, and high concentrations of soluble Zn, Cu, and Cd. The toxicity bioassays with *Lactuca sativa* and soil respiration indicate no toxic effect in the recovered areas, but significant toxic effect were detected in the bare soils, where the non-carbonate area showed higher toxicity than the carbonate sector. Thus, the unrecovered soils have become major sources of pollution, requiring intervention in order to raise the pH, decrease the solubility of pollutants, and encourage colonization by vegetation.

### When organic contaminants interact with particles: consequences on fate, exposure and effects (PC)

#### TUPC25

##### Combined effects of nanomaterials and contaminants in the environment: Interactions with regard to internalization and effects in environmental organisms

D. Kühnel, Helmholtz-Centre for Environmental Research / Bioanalytical Ecotoxicology; S. Böhme, Bioanalytical Ecotoxicology  
Numerous chemicals are already released into our environment and engineered nanomaterials (ENMs) are a group of substances with expected increasing release. Both, certain chemicals and nanomaterials are known to exert adverse effects on environmental organisms. Little is known on the combined effects ENMs and chemical may exert in environmental organism upon interaction. E.g., ENMs are suspected to act as carriers for pollutants, facilitating their uptake and subsequently increasing their toxicity ('Trojan horse' mechanism). Opposed to that, also decreased bioavailability due to the sorption of contaminants to ENMs resulting in a reduced toxicity, were described. Hence, a review of existing literature was conducted in order to evaluate the current state of knowledge. Overall, 95 studies assessing combined exposures of ENMs and pollutants in environmental *in vitro* and *in vivo* models were collected. The chemical substances were classified as polar and nonpolar organic compounds, drugs, as well as inorganic substances and heavy metals. The classes of nanomaterials included were carbonaceous materials (e.g. SWCNTs, MWCNTs), metal and metal oxide particles (e.g. AuNPs, TiO<sub>2</sub>), semi-conductor nanocrystals (e.g. quantum dots), and polymers. The influence of a combined exposure was assessed with regard to contaminant bioavailability, bioaccumulation, and toxicity by differentiating between additive, synergistic, antagonistic and no effects. The aim was to give an overview on combined effects observed between ENMs and pollutants, classify the most common mechanisms, and accordingly deduce recommendation for future research on mixture toxicity. From the reviewed studies it can be concluded, that ENMs and chemicals do interact in most cases and that toxicity of one or both components is modified by the interaction. Evidence for both, enhanced and reduced toxicity of a given compound in the presence of ENM was found. However, only few studies assess both, bioaccumulation and toxicity, hence direct links to compound uptake were not possible in most cases. As a conclusion, we consider it inevitable to determine internal doses of both, the ENM and the compound. This will improve the interpretation of toxicological results (assigning effects to NM, the contaminant or both). In addition, a more detailed description of the physical-chemical interaction of a compound and an ENM is demanded. Keywords: combined effects, mixture

**TUPC26****Adsorption of phenanthrene to carbon nanotubes: Influence on PAH bioavailability and ecotoxicity**

A. Booth, SINTEF Materials and Chemistry / Environmental Technology; B. Glomstad, F. Zindler, Norwegian University of Science and Technology; D. Altin, Biotrix AS; L. Støen, SINTEF Materials and Chemistry / Environmental Technology

In the present study, adsorption of dissolved phenanthrene to aqueous dispersions of a suite of different CNTs containing dissolved natural organic matter (NOM) was investigated. The study also investigated the influence of the adsorption process on the bioavailability and subsequent ecotoxicity of dissolved phenanthrene to standard freshwater test species representing two different trophic levels; the microalga *Pseudokirchneriella subcapitata* and the cladoceran water flea *Daphnia magna*. The dispersion concentration and stability of the different CNTs in different ecotoxicity media was determined with and without NOM present. In addition, the direct ecotoxicity of the CNT suite was investigated with both species at environmentally realistic dispersion concentrations. The influence of CNT surface area and surface chemistry on phenanthrene adsorption and its subsequent ecotoxicity were investigated. Five different CNTs, including one single walled carbon nanotube (SWCNT), two multi walled carbon nanotubes (MWCNT-2 and MWCNT-3) and two functionalised MWCNTs (MWCNT-OH and MWCNT-COOH) were used in the study. Specific surface area and surface chemistry of the CNTs appeared to be important factors in controlling both the fate of CNTs (dispersion concentration and dispersion stability) and their interaction with phenanthrene in aqueous environments. Polar surface functional groups increased the dispersion and stability of CNTs, but reduced their adsorption capacity for phenanthrene. The higher specific surface area of SWCNT compared to the MWCNTs was related to higher phenanthrene adsorption. The CNT having the highest surface area also exhibited the lowest dispersion concentration and the lowest stability in aqueous media over time. A significant change in phenanthrene toxicity to *P. subcapitata* was only seen in the presence of one type of CNT (SWCNT) when considering total phenanthrene concentration in the system. Based on the measured concentrations of phenanthrene in the water phase, however, an increase in toxicity in the presence of CNTs was observed relative to phenanthrene only. This indicates that not only the phenanthrene remaining in the water, but also the phenanthrene adsorbed to CNTs, is available to the algae. An increased exposure concentration to algae attached to CNT aggregates might explain the increased toxicity observed based on the dissolved phenanthrene concentration. Data for *D. magna* are currently being generated.

**TUPC27****Do nanoparticles affect the toxicity of neonicotinoid insecticides?**

C.S. Lorenz, Universität Tübingen / Animal Physiological Ecology; L. Jäger, Tübingen University / Animal Physiological Ecology; L. Guluzada, Tübingen University / Center for Applied Geosciences; L. Luo, Tübingen University / Institute of Inorganic Chemistry; Y. Liang, Tübingen University / Institute of Inorganic Chemistry; R. Anwender, Tübingen University / Institute of Inorganic Chemistry; S. Haderlein, University of Tübingen; H. Köhler, University of Tübingen / Animal Physiological Ecology

Artificial nanoscale particles are frequently in use nowadays and have various areas of application. However, little is known about their fate and interactions in the environment. The objective of this study is to investigate, how the toxicity of the neonicotinoid insecticides imidacloprid and thiacloprid is altered by nanoparticles that potentially adsorb these insecticides. Effects will be examined on the non-biting midge, *Chironomus riparius*, a well-established study organism in ecotoxicology, for which the impacts of these neonicotinoid insecticides are already known. Hence, based on the OECD guideline 218, we examine several endpoints in the life cycle of *C. riparius* including survival rate, weight gain, emergence rate, and the induction of the stress protein hsp70 as a marker for proteotoxicity. Tests with the neonicotinoid insecticides or nanoparticles as single substances are conducted, followed by experiments with mixtures of them. For the latter experiments, one can hypothesize that nanoparticles enter an organism easily due to their small size, thereby increasing the uptake of insecticides associated to the nanoparticles. Consequently, the nanoparticles would act as 'Trojan horses', and the efficiency of the insecticides may be increased. Another possible mixture effect could be that the nanoparticles are largely excluded from uptake by the epithelia of *C. riparius*. Consequently, less insecticides would be bioavailable to the midges, resulting in weaker toxicity. Moreover, in future experiments, nanoparticles with a fluorescent core will be used which enables to track them in the organisms.

**TUPC28****Fullerene soot modifies the toxicity of organic xenobiotics in ecologically relevant conditions**

J. Sanchís, M. Olmos, IDAEA CSIC / Water and Soil Quality Research Group; M. Farre, IDAEA-CSIC; D. Barcelo, IIQAB-CSIC / Institute for Environmental Assessment and Water Research

Fullerenes are carbon nanomaterials with relevant scientific interest and potential market applications in fields as diverse as personal-care products, water treatment, electronics and solar cells. Because of their use in nanotechnology and their

incidental emission from combustion sources, fullerenes can be found in the environment. This has raised health and environmental concerns and many studies have been recently conducted in order to assess the toxicity of fullerenes to different organisms. Nevertheless, these tests have often been conducted in non-realistic conditions, suspending fullerenes in water with the help of surfactants, ultrasound or by solvent-transfer method. In the present work, the acute toxicity of fullerene soot has been tested simulating ecologically relevant scenarios. Fullerenes were dispersed by intensive stirring during several weeks, with aeration and sunlight exposure, in artificial sea water, artificial estuary water and artificial fresh water, with different concentrations of organic matter. Their toxicity to *Vibrio fischeri* and *Daphnia magna* was assessed by means of standardized tests. Fullerenes toxicity was highly dependent on both, salinity and humic acid concentrations, following the DLVO theory, and EC<sub>50</sub> were slightly different than those obtained in the bibliography, highlighting the relevance of suspending nanomaterials in environmentally extrapolable conditions. Moreover, the toxicity of binary mixtures fullerene soot-organic pollutants was assessed with five xenobiotics. In most of the cases, fullerenes aggregates immobilized the organic pollutant because of their sorptive properties and the activity of pesticides was severely inhibited. However, in some particular cases, a synergism between fullerene aggregates and the organic pollutant was observed in *Daphnia magna*. This situation strongly suggested that fullerenes, when bioaccumulated in daphnids digestive tract, may act as vectors for other pollutants, enhancing their uptake and toxic effects, what is known as Trojan Horse Effect.

**TUPC29****Preliminary study on the interaction of Carbon Black nanoparticles and B(a)P on zebrafish embryos**

C. Della Torre, University of Siena / Department of Physical Earth and Environmental Sciences; L. Del Giacco, University of Milan; N. Santo, Università degli Studi di Milano; S. Magni, M. Ascagni, A. Ghilardi, L. Prosperi, D. Maggioni, University of Milan; M. Parolini, University of Milan / Biology; A. Binelli, University of Milan / Department of Biosciences

Carbon Black Nanoparticles (CBNs) have been investigated as benchmark control for *in vivo* toxicological evaluation of diesel exhaust particles and as a model of urban air pollution particulate matter. On the contrary their toxicity for aquatic biota is almost unknown. CBNs are ROS generators and can mediate genotoxicity by means of inflammation and oxidative stress. Moreover CBNs show strong sorption capacity to organic pollutants as PAHs. Therefore in the ternary system organism-pollutant- CBNs two interactions are possible: CBNs might act as carrier of toxic pollutants inside the cell, thus producing synergistic adverse effects. Otherwise CBNs could bind the compound decreasing its bioavailability for biota. The aim of this study is therefore to evaluate the contribution of toxic environmental pollutant as B(a)P to CBNs toxicity and vice-versa on zebrafish (*Danio rerio*) embryos. Firstly, CBNs standard was cleaned-up with toluene in a Soxhlet extractor up to 92 h, evaluating the effective elimination of PAHs impurities by a GC-MS/MS. Results highlighted a strong sorption of PAHs to CBNs standard and the need to purify it before the following exposure tests. The ΣPAHs in CBNs accounted for 0.1% of total carbon mass. The concentration of low molecular weight PAHs was drastically reduced within 24 h of toluene extraction, while high molecular weight PAHs were efficiently removed after 48 h of clean-up. The ΣPAHs in CBNs after 92 h of toluene clean-up resulted 0.0003% of carbon mass. Embryos were then treated under semistatic conditions with purified CBNs at concentration of 10 and 20 mg/L and separately with benzo(a)pyrene (B(a)P) at concentration of 5-5000 µg/L in DMSO. Particles characterization by DLS showed that CBNs in zebrafish water (zw) resulted fairly stable and dispersed with a Z-average up to 200 nm. The ζ potential indicated a negative surface charge. Treated and control embryos were visually assessed for malformation at different times (24, 48, 72, and 96 hours post fertilization) under stereomicroscope, transmitted light microscope and fluorescence microscope. The uptake of CBNs and B(a)P and their intra-cellular or tissue target, as well as the possible damage of the biological structures have been investigated by means of advanced microscopy techniques. Our results highlight that the contribution of the sorbed environmental contaminants to CBNs toxicity represents a key feature in the ecotoxicological studies.

**From ecosystem services to risk assessment for aquatic and terrestrial plants (PC)****TUPC31****ECOSYSTEM SERVICES, ENVIRONMENTAL STRESSORS AND DECISION MAKING - RESULTS OF A GLOBAL SETAC AND ESA PELLSTON WORKSHOP**

J. Van Wensem, TCB; C.S. Duke, Ecological Society of America; E. Huber-Sannwald, Instituto Potosino de Investigación Científica y Tecnológica (IPICYT); L. Kapustka, LK Consultancy; L. Maltby, The University of Sheffield / Dept of Animal Plant Sciences; D.W. Moore, ENVIRON International Corp.; W.R. Munns, U.S. EPA / Atlantic Ecology Division

There is increasing awareness that improved environmental management can be achieved by considering more explicitly the benefits that humans receive from ecosystems. In a broad sense, the contributions of ecological systems to the health

and well being of people can be considered ecosystem goods and services (hereafter ecosystem services). The ecosystem service concept provides a framework for considering whole ecosystems in decision making, for valuing the services they provide, and for ensuring that society can maintain a healthy and resilient natural environment now and for future generations. A Pellston Workshop was convened by SETAC and the Ecological Society of America (ESA) in Shepherdstown, WV, USA, at the end of September 2014 to develop: 1) broad consensus about, and practical guidance for, the application of the ecosystem services concept to environmental decision making as part of a movement towards environmental sustainability; and 2) work products in the form of scientific manuscripts, booklets, and presentation materials needed to promote environmental stewardship through application of the ecosystem services concept by the memberships of SETAC and ESA globally, and society more generally. Thirty participants from academia, government, industry, and NGOs around the world worked toward consensus on a path forward for putting the ecosystem services concept to practical use in decision making. Individual workgroups considered five main topics: 1) ecosystem services, protection goals and environmental decision making; 2) understanding and applying ecological production functions; 3) applying the ecosystem services concept to risk assessment; 4) applying the ecosystem services concept in natural resource management and restoration; and 5) practical guidance for applying the ecosystem services concept in environmental decision making. This presentation highlights the key findings and recommendations of each workgroup, together with overall recommendations for improving the use of ecosystem services in decision making.

### TUPC32

#### **Modelling the impact of herbicide exposure on the structure and composition of non-target terrestrial plant communities**

J. Reeg; K. Bergholz, University of Potsdam; T. Schad, EnSA; K. Körner, University of Potsdam; A. Solga, Ecology; T.G. Preuss, Bayer CropScience / Environmental Modelling; F. Jeltsch, University of Potsdam

Analyzing the impact of herbicide exposure on ecosystem services provided by plants is gaining increasing importance in ecological risk assessment of pesticides. Stakeholders currently discuss the necessity to not only consider direct impacts of herbicides on plant individuals and populations but also effects emerging from inter- and intraspecific interactions, i.e. community-level endpoints such as diversity, structure and composition. We linked a spatiotemporally explicit drift exposure model (Xplicit) to an individual-based grassland community model (IBC-grass). Thereby we analyzed impacts of herbicide drift on structure and composition of non-target plant communities. Based on an extensive literature review of herbaceous field boundaries in Europe, a representative field-edge community of perennial plant species was derived and parameterized into the trait-based approach of IBC-grass. Variable herbicide exposure and its impact on individual-level was calculated with Xplicit and species effect distributions were generated. These individual-level effects were transferred to individuals of plants, seedlings and seeds within IBC-grass in order to simulate community effects of realistic herbicide drift events. Short-term effects of herbicide exposure on the structure and composition of the plant communities were closely linked to distance to field edge. On patches immediately at the field edge, the simulated plant functional type community showed a long-term change in structure and composition. A decrease in evenness indicates that abundance is more unevenly distributed among the PFTs. In contrast, with some meters distance only minor and transient effects could be detected. The mechanistic modelling approach indicates that the species composition and abundance within field boundaries can be impacted by agricultural practices such as herbicide applications. Modelling approaches such as IBC-grass can be useful tools to evaluate the importance of assessing community-level endpoints in real-world context in ecological risk characterizations.

### TUPC33

#### **Ecosystem services for aquatic macrophytes: linking ecology to risk assessment of chemicals**

G.H. Arts, Alterra Wageningen University and Research Centre / Environmental Risk Assessment; J. Wolters, University of Antwerp / Department of Biology

Derivation of protection goals based on the ecosystem services approach has been accepted in pesticide risk assessment recently. Ecosystem services are the benefits people obtain from ecosystem structures and processes. However, up to now, this ecosystem services approach has been applied more qualitatively than quantitatively. Risk assessment could benefit from a more quantitative approach i.e. the quantification of important ecosystem services. Here we focus on aquatic macrophytes as important key service providing units (SPUs). A literature research was performed in order to collate quantitative information related to ecosystem services provided by three different types of aquatic macrophyte vegetation: seagrass beds as a representative of submerged macrophyte vegetation; duckweed vegetation as a representative of floating macrophyte layers; reed as a representative of emergent macrophyte stands. Quantitative information was collated and categorized into provisioning, regulating, cultural and supporting services. These ecosystem services will be presented and used as an example how to link this information to the risk assessment of chemicals. Aquatic macrophytes deliver a number of ecosystem services that make them important service providing units (SPUs) in aquatic ecosystems. Provisioning services were common use and

economically favourable in former times (e.g. mattress stuffing, thatching) and are becoming more popular recently (proteins). A number of regulating services include carbon fixation and storage, primary production and nutrient retention. In order link ecosystem services to risk assessment quantitatively, macrophyte assessment endpoints need to be linked to SPUs. Biomass seems to be a promising endpoint, as it is included as one of the assessment endpoints in the protection goals, can be linked to the ecosystem services provided by aquatic macrophytes and is an important output of macrophyte models assessing the effects of chemicals. This approach needs further elaboration and quantification.

### TUPC34

#### **Further developments in the risk assessment of pesticides to non-target terrestrial plants**

M. Arena, EFSA - European Food Safety Authority / Pesticides; D. Auteri, Auteri / Pesticides Unit; A. Ippolito, EFSA - European Food Safety Authority / Institute for Environment and Sustainability IES; R. Luttik; R. Sharp, EFSA - European Food Safety Authority / Pesticides Unit; F. Streissl, EFSA / Pesticides Unit; C. Szentes, Pesticides Unit

The EFSA Panel on Plant Protection Products and their Residues (PPR) issued in 2014 an opinion on the state of the science for the risk assessment for non-target terrestrial plants (NTTPs) as a precursor to developing a new guidance document. The general protection goal for NTTPs is the maintenance of biodiversity in the agricultural area. Specific protection goals based on ecosystem services were identified for both the off-field and in-field NTTPs including endangered plant species. Non target terrestrial plants were considered key drivers for nutrient cycling, water regulation, food web support, aesthetic values and genetic resources. To address these specific protection goals, the opinion indicated that further developments might be needed on test methods. Several shortcomings in the available test guidelines have been identified such as use of crop species as surrogates for wild herbaceous and woody species and non crop species. In addition, tests are of limited duration and do not allow for the assessment of more sensitive endpoints such as seed production, germinability and other reproductive endpoints. Data collected in the opinion on both vegetative and reproductive endpoints demonstrated the importance of considering reproductive endpoints in regulatory assessment. To bridge the current gap, extrapolation factors were proposed by the PPR Panel to be applied to the vegetative vigour endpoints, which are currently used for the risk assessment, to compensate for higher sensitivity of reproductive endpoints. Furthermore, the opinion included an inventory of higher tier tests and identified other potential routes of exposure such as vapour- and dust drift which will need further consideration in a risk assessment scheme.

### TUPC35

#### **An ecosystem services approach to pesticide risk assessment and risk management of non-target terrestrial plants: recommendations from a SETAC Europe workshop**

L. Maltby, The University of Sheffield / Dpt of Animal Plant Sciences; G.H. Arts, Alterra Wageningen University and Research Centre / Environmental Risk Assessment; M. Dollinger, Bayer CropScience; E. Kohlschmid, Agroscope / Institute for Plant Production Sciences IPS; H. Ochoa-Acuna, DuPont Crop Protection / Veterinary Pathobiology; V. Poulsen, ANSES / French Agency for Food Environmental and Occupational Health Safety

The registration of Plant Protection Products (PPPs) in the EU is under Regulation 1107/2009, which recommends a tiered approach to assessing the risk to non-target terrestrial plants (NTTPs). However, little information is provided on how to perform and implement higher tier studies or how to use them to refine the risk assessments. Therefore a stakeholder workshop was organized to consolidate current knowledge and expertise to aid the further development of testing and assessment procedures for NTTPs. The agreed recommendations of the workshop relate to the three main themes, i.e. specific protection goals, risk assessment and mitigation. The participants of the workshop adopted the European Food Safety Authority (EFSA) approach of using an ecosystem services framework for identifying specific protection goals. First, delivery and protection of ecosystem services were discussed for in-crop, in-field and off-crop, and off-field areas. Second, lower and higher tier risk assessment methods, including modelling approaches, were evaluated. Third, options for risk mitigation of spray drift and run-off were discussed and evaluated. NTTPs provide a wide range of provisioning, regulating, cultural and supporting ecosystem services and may occur in-crop, off-crop/in-field and off-field. The workshop participants agreed that the type and relative importance of ecosystem services provided by NTTPs differ between different areas both in field and off field. A number of higher-tier options were identified and the benefits from these options addressed. A number of concerns were raised around these options and actions taken in order to reduce uncertainty. For the initial tiers, concern was especially raised around uncertainty related to test species (are standard test species protective for wild species?) and endpoints (are current regulatory endpoints protective of reproductive endpoints?). At the level of field- or other multispecies-studies, participants concluded that these studies pose a challenge due to limited experience with this type of study and the absence of guidelines (what to measure and how?). Related to exposure, the main question was what is the relative importance of different exposure pathways to non-target terrestrial plants? These questions were translated into specific actions including collating and reviewing data and literature. The workshop report is foreseen for the

first months of 2015 and will include the outcome of the specific actions.

#### TUPC36

##### **Sensitivity of wild plant and crop species to plant protection products - Literature review and analysis for SETAC AG Plants**

H. Christl, Tier3 Solutions GmbH

1 on behalf of the SETAC workshop on “Non-target terrestrial plants” Following recommendations of the SETAC workshop on “Non-target terrestrial plants” a literature review was performed to compare the sensitivity of terrestrial plant species (crop species and wild species), aiming to test the hypothesis that wild plant species could be more sensitive to plant protection products (PPPs) than the standard test species - which generally, though not exclusively, are crop species. Literature data recording endpoints of crop and of wild species were collected, implemented in a database and merged with regulatory data provided by the Crop Life International NTP group, resulting in a dataset as comprehensive as possible. A total of 2048 species/a.s. test combinations were included in the data base, some with just one, others with several endpoints (e.g. ER25, ER50, shoot height, biomass etc.), comprising 49 herbicides. Endpoints of crop and wild species were compared individually by active substance, testing different endpoint types. The majority of data was available for ER25 and ER50 endpoints, based on biomass measurements of vegetative vigour lab and field studies, hence the assessment focussed on these. The assessment was based either on the most sensitive species each, or on the average sensitivity of the group. Differences in sensitivity were expressed by means of a quotient, dividing the crop endpoint by the wild species endpoint. Quotients below “1” indicate cases where crop species were more sensitive than wild species (i.e. crop endpoints lower than wild species’ endpoints), quotients above “1” indicate that wild species were more sensitive than crop species. Average quotients were found generally to be close to 1, with deviations in both directions. The overall conclusion was that, based on ER25 and ER50 endpoints (biomass VV) and the available extensive data sets, no consistent differences in sensitivity between crop species and wild plant species were detected.

#### **Multistress in aquatic environments: the big picture (PC)**

##### **WEPC01**

##### **Effects of environmental stress on the genomic integrity of *Daphnia magna* (Straus, 1820)**

R. Wolf, Department of Biosciences; T. Andersen, University of Oslo; D.O. Hessen, University of Oslo / Department of Biosciences; K. Hylland, University of Oslo / Biosciences

**Introduction.** Climate change is predicted to cause “browning”, i.e. an increase of dissolved organic carbon (DOC) in aquatic ecosystems. DOC offers protection from UV radiation (UVR), but may itself pose radical stress. One of the most common biochemical consequences linked to UVR, but not yet to DOC, is DNA damage. Using the limnic cladoceran *Daphnia magna*, this damage is investigated by applying the comet assay, a single cell gel electrophoresis that can account for both single and double strand breaks. A more delicate feature linked to genomic damage is histone modifications such as  $\gamma$ H2A.X, which mediates DNA repair response. Our study investigates the influence of DOC and UVR on DNA damage and  $\gamma$ H2A.X levels in *Daphnia*. **Materials and methods.** Adult *Daphnia* were placed in 2 ml 96-well plates, and exposed to DOC (10 mg L<sup>-1</sup>), UVR ( $\lambda = 390$  nm), or a mixture of both. The comet assay was performed using a modified, high-throughput protocol. Investigation of histone modifications was carried out using standard western blot and semi-quantitative ELISA techniques. **Results and discussion.** DNA damage in control groups remained low, while UVR resulted in the highest increase of damage. This effect was buffered in a co-exposure to both DOC and UVR, while DOC itself also led to increased damage. Statistical differences were found between all exposure scenarios. We also showed the effects of UVR and DOC on histone modifications. Using antibodies specific towards human  $\gamma$ H2A.X, we demonstrated the existence of this histone modification in *Daphnia*. We also investigated the influence of different climate change scenarios on  $\gamma$ H2A.X. The results of this procedure will be shown at the conference. **Conclusions.** Our study shows that exposure to DOC and UVR have detrimental effects on the genomic integrity of *Daphnia*. In a broader context, it is important to address how changes in the environment may potentially alter the effects of pollutants in aquatic ecosystems. Elevated levels of DOC imply an increased mobilization and export of terrestrially derived heavy metals and organic pollutants. Our study demonstrates the complexity of stress responses, and by connecting established biomarkers with up-and-coming molecular methods, we work towards pathing the way for future research by further bridging the gap between ecology and toxicology.

##### **WEPC02**

##### **The effects of salinity, temperature and acidification on the regenerative capacity of the polychaete *Diopatra neapolitana***

A. Pires, Universidade de Aveiro / Biologia; E. Figueira, CESAM University of Aveiro; A. Moreira, CESAM Department of Biology; A.M. Soares, Universidade de Aveiro / Department of Biology and CESAM; R. Freitas, Biology Water acidification, temperature increases and changes in seawater salinity are

expected to occur in the near future. Climate changes can induce risks for aquatic ecosystems, mainly on marine coastal areas, since they are inhabited by a large number of benthic species with ecologic and socio-economical importance. In this context, increasing efforts have been addressed to evaluate the effects of variations in temperature, salinity and pH on biological responses of marine organisms. Essentially due to their life-history characteristics, polychaetes have frequently been used to evaluate the impact of environmental disturbances in estuarine systems. The onuphid polychaete *Diopatra neapolitana* presents a wide spatial distribution, inhabiting intertidal and shallow subtidal habitats and frequently used as fish bait. In previous studies this species demonstrated to be a good bioindicator of metal contamination and organic matter enrichment. However, most of the studies were devoted to bioaccumulation patterns and biochemical alterations, and little is known on *D. neapolitana*'s physiological alterations, namely on the species regenerative capacity, due to environmental changes. Thus, the present study aims to assess the effects of temperature shifts, pH reduction and salinity changes in the tissue's regenerative capacity of this polychaete species. The results obtained demonstrated that all the experimental conditions tested (pH, salinity and temperature) significantly affected the regenerative ability of the polychaete *D. neapolitana*. This study evidenced that *D. neapolitana* individuals exposed to lower pH exhibited significantly lower capacity to regenerate their body, while with the increase of temperature individuals showed a higher capacity to regenerate their tissues. Furthermore, the present work demonstrated that individuals exposed to salinities 28 and 35 did not present significant differences between them, while salinities 21 and 42 influenced negatively the regenerative capacity of *D. neapolitana*. At the end of regeneration, comparing all conditions, high salinity (42) seemed to have a greater impact on the regenerative capacity of individuals than the other factors, since under this condition individuals took longer to completely regenerate. Overall, this study demonstrated that variations in abiotic factors can strongly affect *D. neapolitana*'s performance. **Keywords:** Polychaetes, body regeneration, biomarker, climate change

##### **WEPC03**

##### **Metal contamination of in situ caged *Gammarus fossarum* as an indicator to predict ecological disturbance: a national scale case-study**

A. Ciliberti, Irstea Lyon / UR MALY Laboratoire Ecotoxicologie; A. Chandresris, Irstea Lyon; M. Coquery, Irstea centre de Lyon Villeurbanne / UR MALY; R. Recoura-Massaquant, Irstea centre de Lyon Villeurbanne / UR MALY Laboratoire Ecotoxicologie; Q. Chabanne, Irstea Lyon; A. Francois, Irstea centre de Lyon Villeurbanne / UR MALY Laboratoire Ecotoxicologie; a. chaumot, O. Geffard, Irstea / UR MALY Laboratoire Ecotoxicologie

Comprehension and prediction of ecological effects related to environmental contamination calls for improvement of risk assessment approaches and validation of existing methods. As regards to metals, the prediction of ecological disturbance through the assessment of bioavailability is limited to the use of approaches not successfully validated *in situ*. Metal-related risk assessments should integrate results from field studies about the relationship between bioavailable concentrations and ecological response. In this aim, 1/ biota (which reflect bioaccumulation and bioavailability) should be used to estimate water contamination level, and 2/ the relationship between concentrations in biota and ecological response should be characterised. The validation of this approach at a wide scale could reveal the existence of a universal threshold for metal concentrations in a given biomonitor above which adverse ecological effects appear. Previous studies mainly rely on passive biomonitoring: the presence of the test organism is required *in situ* and the influence of confounding factors may be neglected. Active biomonitoring with transplanted organisms collected from the same population enables to overcome these drawbacks. Our work aimed at calibrating the active biomonitor *Gammarus fossarum* by relating the concentrations measured *in situ* caged organisms to local ecological indicators. 129 sites were investigated in France, for which relevant ecological and chemical data were available. Controlled batches of gammarids were exposed during 7 days. Metals were analysed by ICP-MS (Cd, Pb, Ni, Co, Ag, As, Zn, Cr, Cu) or automated AAS (Hg). For most metals, bioaccumulation was significant with ratios between the lowest and the highest values related to the essential or non-essential character of the metals, confirming the relevance of this species to monitor metal contamination in freshwater systems. For all metals, results showed no relationship between bioaccumulation levels and global ecological disturbance. On the contrary, for Cd and Pb, a clear relationship was established between the concentration in caged organisms and the abundance of metal-sensitive invertebrates. Metal concentration in *G. fossarum* can be quantitatively related to metal-specific adverse responses in stream invertebrates. Dose-response curves, defined for each metal at the national scale, indicate that contamination measured in caged organisms could be used to manage the risk of metallic contamination.

##### **WEPC04**

##### **Bioaccumulation of organic pollutants in present-day and climate altered food webs**

A.M. Berglund, Umea University / Department of Ecology and Environmental Science; M. Ripszám, Umea University / Department of Chemistry; C. Gallampois, Umea University / Chemistry; A. Andersson, Umea University / Ecology and Environmental Science; E. Griniene, D. Figueroa, P. Byström, Umea University / Department of Ecology and Environmental Science; P. Haglund, Department of

Chemistry; M. Tysklind, Umea University / Department of Chemistry  
We examined the effects of a warming climate on the accumulation of organic pollutants (OPs) in the Baltic Sea. This region has a long history of pollution and is highly influenced by river run-off. With the proposed changes in climate (increased temperature and precipitation) a larger river discharge to the sea is expected, hence an increased inflow of OPs and dissolved organic matter (DOC) of terrestrial origin. Earlier studies have shown that increased temperature and DOC results in a shift at the base of the food web, favoring bacteria over phytoplankton. This creates a web with more trophic levels. Thus, in theory, top consumers in a bacteria-based food web could be subjected to pollutants at higher concentrations than in a phytoplankton dominated system, provided that the contaminants biomagnify. In this mesocosm-study we exposed a marine community (from bacteria and phytoplankton to fish) for a cocktail of legacy and emerging OPs, using different climate scenarios (increased temperature and DOC). We found evidence for a bacteria favored food web with increasing DOC, but the bioaccumulation factor (BAF) of OPs were not higher in fish from DOC-treated mesocosms. If any, higher temperatures resulted in increased BAFs in fish but at higher temperatures DOC generally reduced the bioaccumulation. Thus, increased temperature may be an important factor for bioaccumulation of OPs in fish and the effect of DOC is complex and needs further investigations.

#### WEPC05

##### **Linking multiple stressors to microbial community structure for water quality assessment**

A. Barra Caracciolo, National Research Council / Water Research Institute; V.E. Ferrero, IES; P. Grenni, National Research Council of Italy (CNR) / Water Research Institute; M. Di Lenola, National Research Council / Water Research Institute; N. Adeollo, National Research Council of Italy / Water Research Institute; L. Patrolecco, Water Research Institute Italian National Research Council; R. Loos, European Commission DG Joint Research Centre / Institute for Environment and Sustainability; S. Tavazzi, European Commission DG Joint Research Centre; J. Pinto Grande, European Commission Joint Research Centre Institute for Environment and Sustainability; M.L. Saccà, National Research Council / National Water Research Institute; t. Iettieri, European Commission - Joint Research Centre / Institute for Environment and Sustainability

Freshwater quality assessment in Europe is established under the Water Framework Directive (WFD) based on measurements of chemical pollutants in sediments and water and biota (chemical status) and on the ecological indicators such as nutrients, temperature, species compositions etc. (ecological status). However in the current strategy a link between chemical and ecological status is missing. No biological indicators are foreseen to integrate the different anthropogenic pressures including chemical mixture, nutrients, temperature changes in order to provide a global scenario on the ecosystem and therefore on the water quality. In this context, MicroCokit FP7-PEOPLE-2012-IAPP project is focused on the identification of microbial community based indicators for monitoring and evaluating the complexity of multiple stressors (e.g. chemical pollutants, temperature, nutrients etc.) relevant to guide preventive and remediation actions by the water authorities. For this purpose the river Tiber has been chosen as a pilot case study and sampling sites were selected based on different anthropogenic pressures which they are exposed to. Water samples are being analyzed for both microbiological (FISH analysis and Metagenomic) and chemical analysis (organic and inorganic compounds, including emerging pollutants). Within the 4-years project, two campaigns are contemplated per year (Autumn and Spring). We report preliminary results of the chemical analyses (inorganic elements, DOC, PAHs, organochlorine, triazine, chloroacetamide pesticides, perfluorinated compounds, pharmaceuticals, etc.) and epifluorescence direct microscopy analyses (total microbial abundance and phylogenetic community characterization by FISH) regarding the first two campaigns. The preliminary results suggest that the microbial community structure reflects both natural environmental variations (river course and seasonality) and anthropogenic pressures. The same water samples are currently being processed for metagenomic analysis in order to obtain a broader description of the microbial community to be compared with the overall chemical results.

#### WEPC06

##### **Airborne pollution-driven basal feminization in natural lake trout populations from European mountain lakes**

S. Jarque, Masaryk University / Faculty of Science RECETOX; E. Gallego, IDAEA-CSIC / Department of Environmental Chemistry; J. Grimalt, IDAEA-CSIC; B. Pina, IDAEA-CSIC / Environmental Chemistry  
Gene expression levels of vitellogenin (Vtg) and Zona radiata protein 1 (Zrp) in liver were measured in brown trout (62 males and 81 females) from different lakes and brooks in four distant European mountain areas in Norway, Tyrol (Austria), Tatra Mountains (Slovakia/Poland) and the Pyrennes (Spain). As expected, expression of both genes was several orders of magnitude higher in mature females than in males, whereas females in the early stages of egg-formation showed levels of Vtg and Zrp expression close to male levels. Relatively high Zrp expression in males correlated with the presence of OCs in fish muscle, in agreement with previous reports that linked these compounds with estrogenic activity in fish muscle. Analysis of estrogen receptor expression in males corroborated the induction of estrogen-responsive genes in highly polluted male trout. Our data indicate an incipient feminisation of high mountain male trout, and constitute the

first report of endocrine disruption associated exclusively to airborne pollution. The relatively mild nature of the observed feminisation suggests that it may not constitute a direct threat to the fertility of the impacted animals, but this situation may be clearly degraded if a massive redistribution of pollutants currently stored in the sediments should occur.

##### **Determination of contaminants of emerging concern in soil substrate and plant material by QuEChERS extraction followed by liquid chromatography quadrupole linear ion trap tandem mass spectrometry**

A. Martínez-Piñeros, University of Almería; A. Agüera, University of Almería / Chemistry and Physics; P. Fernandez, IDAECSIC / Environmental Chemistry; S. Malato, Plataforma Solar de Almería-CIEMAT

Presence of unregulated and not assessed contaminants of emerging concern (CECs) in wastewater effluents represents a significant challenge to wastewater reclamation. Problems associated to the repeated release of treated wastewater in the environment for reuse applications, such as irrigation practices, are still scarcely investigated. Therefore, the accumulation of contaminants in soils after irrigation and the evaluation of the uptake by crop plants are new insights that demand research in order to evaluate the possible risks for environment and human health. Consequently, comprehensive and high-throughput analytical methods have to be developed and validated to provide a comprehensive evaluation of these microcontaminants in soils and crops. With this regard, the main difficulties associated to CECs analysis are the low concentration levels at which they are present and the complexity of the matrices which present great challenges due to high contents of pigments, and fatty or waxy materials, which may induce severe matrix interferences. Therefore, sample preparation methods able to eliminate potential interferences while permit to improve isolation and extraction of target compounds are required. In addition to conventional solid liquid extraction, other instrumental methods such as pressurized liquid extraction or microwave-assisted extraction have been applied to solid samples, but they usually require an additional clean-up step after extraction. QuEChERS (quick, easy, cheap, effective, rugged and safe) is an extraction and clean-up technique originally developed for recovering pesticide residues from fruits and vegetables, but in the last years is rapidly expanding its field of application to other compounds and matrices of environmental concern. In this work, the QuEChERS extraction method has been adapted and optimized for the extraction of a set of CECs in both soil substrate and plant material (lettuce). Optimization of the dSPE clean-up step has been performed by using various phases (PSA, C18, ZSep+). Efficiency was evaluated based on the recovery of the target analytes and matrix effects. The analysis was performed by liquid chromatography quadrupole-linear ion trap tandem mass spectrometry (LC-QqLIT-MS). The analytical method has been validated with good results in

**WEPC14****Toxicogenomics Analysis Reveals Distinct Impact of Various Disinfection Processes on Effluent**

M. Hu, Department of Civil and Environmental Engineering; A. Jia, University of Arizona; N. Gou, Northeastern University / Civil and Environmental Engineering; J. Lan, Civil Environmental Engineering; S.A. Snyder, University of Arizona / Chemical and Environmental Engineering; A. Gu, Department of Civil & Env Engineering / Department of Civil Env Engineering Biotechnology Initiative Program

Wastewater disinfection has been practiced in U.S. for control of infectious disease. However, the potential adverse effects resulted from disinfection process such as potential toxicity reduction or evolution has not been extensively investigated. In this study, we applied a novel stress gene-based toxicogenomic approach, using GFP-fused *E. coli* reporter cell library, to evaluate the mechanistic toxicity of municipal wastewater effluents disinfected by different technologies, including chlorination ( $\text{Cl}_2$ ), chloramination ( $\text{NH}_2\text{Cl}$ ), ozonation (1.5 mg/L; 6.0 mg/L), ultraviolet irradiation (UV; 250 mJ/cm<sup>2</sup>; 1000 mJ/cm<sup>2</sup>) as well as combination of ultraviolet irradiation and hydrogen peroxide (UV/H<sub>2</sub>O<sub>2</sub>; 10 mg/L & 250 mJ/cm<sup>2</sup>; 10 mg/L & 1000 mJ/cm<sup>2</sup>). The overall toxicity of disinfected secondary effluents was first evaluated by Microtox assay with *V. fischeri* bioluminescence inhibition tests, and the results indicated that no cytotoxicity could be detected with the effluents with enrichment factor less than 25. The toxicogenomics-based molecular toxicity assay was more sensitive than the MicroTox assay and the results showed that compared with raw water, effluents disinfected by chloramination demonstrated a remarkable increase in the total toxicity. In addition, effluent samples treated with UV ( $p < 0.01$ ) as well as UV/H<sub>2</sub>O<sub>2</sub> ( $p < 0.01$ ) also exhibited elevated toxicity than original effluent, particularly with genotoxicity. Interestingly, chlorination ( $p < 0.01$ ) and ozonation ( $p < 0.01$ ) seemed to remove the original toxicity from raw water effectively. The altered gene expression profiles for various effluent samples exhibited distinctive patterns unique for different disinfection processes. Effluents treated by chloramination showed strong responses over all stress categories, especially oxidative stress and DNA damage, while UV and UV/H<sub>2</sub>O<sub>2</sub> elevated genotoxicity. Comparing with UV alone, UV/H<sub>2</sub>O<sub>2</sub> decreased membrane stress related toxicity significantly but the genotoxicity sustained. In summary, this study demonstrated that toxicogenomics-based assay can be applied for detailed and informative toxicity evaluations of water samples and for treatment technology effectiveness assessment.

**WEPC15****Contamination assessment of 3 benthic invertebrates exposed to WWTP effluents by combining targeted and holistic analytical methods: what are the relevance and the feasibility of biological tools?**

A. Berlioz-Barbier, ISA; A. Bulete, Institut des Sciences Analytiques UMR TRACES Team / Service Central d'Analyse; J. Garric, Irstea Lyon; E. Vulliet, CNRS

Nowadays, the pollution of aquatic environment with regard to the input of numerous chemical compound residues in mixture is a growing scientific and societal concern which raises several open questions referring to the potential adverse effects towards non-target organisms. In addition to priority pollutants, new unregulated pollutants, known as "emerging pollutants", are continuously released in the environment via wastewater treatment plant (WWTP) effluents, with a consequent risk for the aquatic ecosystem. Within the water Framework, there are now regulatory arguments in favor of using biota for assessing contamination trends in water bodies, particularly for hydrophobic organic substances. In this context, the aim of the proposed multidisciplinary project was to establish the relevance of 3 benthic invertebrate species to characterize the chemical contamination of water bodies exposed to WWTP effluents. Achieving this goal required to have sensitive analytical methods to enable the detection of a panel of substances in complex matrices. The implementation of targeted analyses based on nanoliquid chromatography (nanoLC) and tandem mass spectrometry has allowed assessing the bioaccumulation of 35 emerging contaminants in 3 invertebrates (*Chironomus riparius*, *Gammarus fossarum*, and *Potamopyrgus antipodarum*). Different exposure campaigns including both caging procedures and laboratory experiments have highlighted the usefulness and the complementarity of biological models selected for monitoring the quality of aquatic environments. Several markers of anthropogenic pollution have been proposed. Moreover, the comparison of bioaccumulation results obtained in laboratory with those obtained in a natural environment showed significant differences that could open discussion on the difficulty to reproduce *in situ* conditions in laboratory. To better understand the response diversity observed during targeted analysis between species, but also between exposure approaches, a metabolite fingerprinting strategy has been implemented using NanoLC coupled to high resolution mass spectrometry. These high-throughput analyses aim to be untargeted and are used as a hypothesis-generating approach. The purpose of this method is not to identify each individual metabolite, but to compare patterns of metabolites that change in a given biological system. In this way, multivariate data analyses have been applied in fingerprinting to determine differences and classify samples.

Nazaret, UMR CNRS 5557 / Laboratory of Microbial Ecology Université Lyon

Spreading of municipal waste materials is a common practice among farmers of developing countries in subsahelian African areas and especially for urban and peri-urban agriculture. Few data are available on their impact on the prevalence of pathogens or antibiotic resistance genes (ARG) in soils under different pedo-climatic contexts than those in northern countries. This study examined the long-term effects of landfill disposal of untreated raw urban wastes on the prevalence of various human opportunistic pathogens (HOP) and ARG in soils from Burkina Faso in regards to the impact on physico-chemical properties. Soils were sampled in amended and unamended fields planted with sorgho at three sites in the periphery of Ouagadougou during campaigns conducted in 2008, 2011 and 2013. At the three sites amendment led to an increase in organic matter, pH, CEC and metal content as well as a significant increase in total heterotrophic bacteria. No coliforms, Enterococci, Streptococci and Staphylococci related indicators were detected. Regarding HOP *P. aeruginosa* was sporadically detected in the amended field at one site in 2011. At one site *Bcc* was detected in the amended fields in 2008 and 2011 and species belonging to *B. cenocepacia*, *B. multivorans*, *B. dolosa*, and *B. latens* were identified. *S. maltophilia* was detected at the 3 sites from the three campaigns, and at a higher level in amended fields. Antibiotic resistance tests showed that *P. aeruginosa* isolates and *Bcc* had a wild type phenotype. Regarding *S. maltophilia* multi-drug resistance was observed with resistance to 7 to 13 antibiotics comparable to the phenotypes of clinical isolates of reference strains. In parallel we investigated the prevalence of ARG encoding for beta-lactams, sulfonamides and quinolones resistance using a qPCR approach. *qnrA*, *qnrB*, *qnrS*, *bla<sub>IMP</sub>*, and *bla<sub>VIM</sub>* were never detected neither in the amendments, nor in the amended and the unamended fields. On the opposite *sul1*, *sul2*, *sul3*, *bla<sub>OXA</sub>*, *bla<sub>TEM</sub>*, and *bla<sub>SHV</sub>* genes were detected at variable frequency and levels (10<sup>3</sup> to more than 10<sup>7</sup> copies.g<sup>-1</sup> soil dry weight) in amended fields and amendments at the 3 sites from all campaigns. These genes were rarely detected in the unamended soils. This study evidenced that amendment might impact directly the dissemination of pathogens and ARG-harboring populations by introducing them from exogenous sources but might indirectly alter their prevalence and properties by modifying environmental conditions.

**WEPC17****Impact of meropenem and zinc levels on resistance development in biofilms in rotating tubular reactors**

C.L. Hands, Civil Engineering and Geosciences; J.R. Snape, AstraZeneca UK Ltd. / AstraZeneca Global Environment; D.W. Graham, Newcastle University / Civil Engineering and Geosciences

Human morbidity and mortality has been substantially reduced since antibiotics were introduced to human therapy almost 60 years ago. However, the efficacy of antibiotics and their effect on public health is now being challenged by the emergence of antibiotic resistant bacteria. Many reports have indicated that elevated heavy metal exposures can promote the development and proliferation of antibiotic resistance (AR). For example, evidence from waste treatment systems show that AR was higher when zinc (Zn) levels were also high. In this study we measured and assessed changes in AR in microbial biofilm communities and effluents, by using an apparatus containing six aerobic rotating tubular reactors that mimic trickling filter beds, to treat domestic sewage with different levels of Zn and meropenem. Mixed domestic primary settled sewage and synthetic sewage was pumped through the reactors, to allow surface biofilms to develop and reach optimal thickness for 21 days, after which the following concentrations were added to each respective tubular reactor; no amendment (control), 2 mg/L meropenem (Reactor 2), 2 mg/L Zn (Reactor 3), 2 mg/L meropenem and 2 mg/L Zn (Reactor 4), 2 mg/L meropenem and 20 mg/L Zn (Reactor 5), 2 mg/L meropenem and 100 mg/L Zn (Reactor 6). Samples for microbiological, metal and molecular analysis were collected once a week from a common influent tank, six effluent flasks and from biofilm at the top end (upper biofilm) and bottom end (lower biofilm) of each reactor and twice a week for chemical analysis. Microbiological analysis used R2A agar plates, amended with meropenem and Zn appropriately and molecular analysis used qPCR with appropriate probes and primers. The study showed that elevated Zn increases meropenem resistance in reactors fed with primary settled domestic sewage and dosed with 2 mg/L of meropenem and Zn up to 100 mg/L. An average of combined meropenem and Zn resistance of 51% was seen when 100 mg/L of Zn was added, while 24% was seen when 20 mg/L of Zn was added, showing that increasing Zn levels result in increased meropenem resistance. The presence of meropenem in these reactors also increased resistance; however it is suspected the main reason for this increase was due to higher concentration of Zn dosed to the reactors. Moreover the presence of Zn alone, caused combined resistance as high as 5%. Elevated Zn levels in domestic sewage clearly increases meropenem resistance levels in treated effluents.

## WEPC18

### Changes in human faecal microbiomes prior to wastewater treatment associated with different antibiotics

f. walsh, Biology

Antibiotics are associated with variations in the bacterial populations in the human gut microbiome. However, within the human microbiome factors other than antibiotics also play their role. When faeces is mixed in a system prior to input into a wastewater treatment plant it is subjected to many contaminants. Antibiotics are emerging contaminants. This study sought to investigate the effects of different antibiotics on the same faecal microbiome. One faecal sample was divided into six equal samples. One of the following antibiotics was added to each of the samples: Ciprofloxacin (Cp) (1 mg/L), ampicillin (A) (8mg/L), tetracycline (T) (4mg/L), Kanamycin (K) (4mg/L), colistin (C)(1mg/L) and no antibiotic (NA). All samples were incubated at 37 °C for 16 hours with shaking. The microbiomes were analysed using 16S rRNA sequencing on an Illumina MiSeq and the data was analysed using the Illumina BaseSpace platform. The number of different species within the treated microbiomes varied: C = 348, K = 314, Cp = 390, T = 363, A = 294 and NA = 361. Increases in the relative abundances (compared to the NA) of the Clostridia were detected in the ampicillin and kanamycin treated samples, increases in Bacteroidia and Actinobacteria in the colistin treated sample. Decreases in the relative abundances of Clostridia were detected in the colistin treated sample, decreases in Bacteroidia in the ampicillin and kanamycin treated samples, decreases in the Flavobacteria in the ampicillin treated samples and decreases in the Actinobacteria in the ampicillin, tetracycline and ciprofloxacin treated samples and decreases in the Bacilli in ampicillin, tetracycline and colistin treated samples. The variations in the composition of the microbiome indicate the potential selective pressure posed by specific antibiotics in the wastewater system prior to treatment, which could alter the antibiotic resistance profile of the influent microbiome. The significance of these results is the potential for selection of increased abundances of specific pathogens or bacteria carrying resistance genes, which are selected by the mixing of human waste with antibiotics at the start of the wastewater system.

### Risk assessment, risk management and mitigation for pesticides: from regulation to public perception (PC)

## WEPC25

### Aminomethylphosphonic acid (AMPA) chronic risk assessment for *Daphnia* and fathead minnow

G. von Mérey, Monsanto Europe S.A. / Regulatory; S.L. Levine, Monsanto Company / Regulatory Sciences; P. Manson, Cheminova AS European Regulatory Office / Global Regulatory Science; P. Sutton, Syngenta; H.O. Krueger, Wildlife International, Ltd. / Aquatic Toxicology; T. Minderhout, Evans Analytical Group EAG

Aminomethylphosphonic acid (AMPA) is the simplest member of a broad class of compounds known as aminomethylenephosphonates and the only environmental metabolite measured in significant amounts during the degradation of the herbicide glyphosate in soil. However, there are additional sources of AMPA in the environment, originating from organic phosphonates which are used in water treatment to inhibit scale formation and corrosion, in the textile industry and in industrial and household detergent formulations. AMPA, like glyphosate, has low acute toxicity to aquatic animals. However, the chronic toxicity of AMPA to aquatic animals has not been evaluated before this study. The purpose of this investigation was to assess the potential for chronic toxicity of AMPA to fathead minnow (*Pimephales promelas*) and *Daphnia magna*, which were used as representative organisms for freshwater fish and aquatic invertebrates respectively. Chronic toxicity to *P. promelas* was evaluated in a fish early life-stage study following the methodology of Organization of Economic Coordination and Development (OECD) test guideline 210. The primary endpoints in the early life stage study were larval survival, growth and development. The NOEC for *P. promelas* was determined to be 12 mg/L, the highest concentration tested. The chronic toxicity to *D. magna* was evaluated in a *Daphnia* reproduction test following the methodology of OECD test guideline 211. The primary endpoints in this study were survival, growth and reproduction. The NOEC for *D. magna* was determined to be 15 mg/L. Conservatively predicted environmental surface water concentrations for AMPA from typical foliar agricultural application rates and values from surface water monitoring programs are 100-1000 times lower than the achieved NOAEC values from both studies. Consequently, there is a large and highly protective margin of safety between realistic environmental exposures to AMPA and chronic toxicity to aquatic vertebrates and invertebrates.

## WEPC26

### Can pyrethroid resistant *Hyalella azteca* accumulate ecologically-relevant pyrethroid tissue concentrations?

M.J. Lydy, Southern Illinois University-Carbondale / Center for Fisheries Aquaculture and Aquatic Sciences; A.D. Harwood, Southern Illinois University / Department of Natural Sciences; S. Nuttle, Southern Illinois University Carbondale / Zoology; L. Muggelberg, Southern Illinois University Carbondale / Department of Zoology

Pyrethroid insecticide resistance has been found in the epibenthic amphipod, *Hyalella azteca* at several locations in California, USA. The resistance is due to a

single-point mutation in the target site gene, the neuronal sodium channel. The objectives of the present study were to take wild caught resistant *Hyalella* and raise them in laboratory culture and examine their relative sensitivity to permethrin over time, quantify permethrin bioaccumulation and biotransformation potential of the resistant compared to non-resistant populations and examine the potential for biomagnification by feeding fathead minnows (*Pimephales promelas*) permethrin-exposed resistant *Hyalella*. Results showed that the resistant population was orders of magnitude less sensitive to permethrin than the non-resistant population and this resistance was maintained over the nine months that the bioassays were performed. The resistant population bioaccumulated 1.5 to 3 times the amount of <sup>14</sup>C-labeled permethrin compared with the non-resistant population at the lower concentrations tested, while biotransformation rates of permethrin were similar among populations. Finally, fatheads minnows accumulated significantly more <sup>14</sup>C-labeled permethrin when fed resistant *Hyalella* dosed with permethrin compared to non-resistant populations due to the fact that the resistant population could tolerate greater permethrin concentrations. This result could cause significant risk to sensitive fish species that consume these hyper-accumulating resistant *Hyalella*.

## WEPC27

### Effects characterization for aquatic invertebrates exposed to imidacloprid-Part B: Higher tier approaches

D. Moore, Intrinsik Environmental, Inc.; L. Knopper, R.L. Breton, Intrinsik Environmental Sciences, Inc.; C. Greer, Intrinsik Environmental Sciences (US), Inc. / Biology; M. Whitfield Aslund, University of Toronto; T. Hall, Bayer CropScience / Environmental Toxicology and Risk Assessment; L.M. Bowers, Bayer CropScience / Environmental Safety

Ecological risk assessment generally moves through a tiered progression from conservative, screening-level analyses to less biased refined analyses. One way to minimize uncertainty, a component of any assessment, is to rely upon multiple lines of evidence. To complete a full weight-of-evidence aquatic invertebrate assessment for imidacloprid, 140 available studies were evaluated for data quality and relevance using a scoring system that assessed four factors: utility, objectivity, clarity and transparency, and integrity. Given the number of mesocosm studies available (n=30), it was possible to develop a taxon-sensitivity distribution (TSD) using acceptable study NOECs. Differences in toxicity of imidacloprid were apparent based on species and exposure duration. Acute toxicity values (LC/EC50) ranged from 2.07 to 169,000 µg/L and chronic values ranged from 0.024 to 47,160 µg/L. Acute and chronic SSDs were derived and an HC5 calculated based on the best fit of four models (i.e., normal, logistic, extreme value and Gumbel models in log space). For the quantitative, higher tier evaluation of the mesocosm results, the most sensitive results (NOECs for emergence, mortality, feeding rate, density and abundance) for 13 taxa in six acceptable studies were used in the derivation of the TSD. The Gumbel model provided the best fit. NOECs were typically determined from nominal concentrations and effects measured from two to 26 weeks. Typically two to four applications were made to the cosm separated by 7, 14 or 21 day intervals. As such, the mesocosm-based TSD can be considered a chronic effects metric. Given that the TSD was based on taxon NOECs, no further safety factors are required to derive the mesocosm-based chronic benchmark for aquatic invertebrates exposed to imidacloprid. These data can also be further assessed using other lines of evidence (e.g., modified Plant Assemblage Toxicity Index suitable for invertebrates) to derived a weight-of-evidence effects metric. For imidacloprid, a large number of higher tier studies (i.e., Tier 3) of good quality are available and provide a level of realism not found in laboratory studies. Using the higher tier mesocosm-based TSD and other lines of evidence produced aquatic effects metrics for imidacloprid that are more ecologically relevant and have lower uncertainty than would effects metrics derived using lower tier approaches.

## WEPC28

### Approach to assess the off-field risk to wild bees from pesticide exposure based on spatial and temporal aspects

B. golla, Institute for Strategies and Technology Assessment; J. Strassmeyer, ral Research Centre for Cultivated Plants / Institute for Strategies and Technology Assessment; C. Saure, Büro für tierökologische Studien; D. Daehmlow, Julius Kühn Institute Federal Research Centre for Cultivated Plants / Institute for Technology Assessment

The amount of natural habitats and the intensity of agriculture is very much landscape dependent. High production areas usually provide less food and nesting habitats especially for solitary bees and bumble bees due to the intensification of agriculture coming together with the establishment of large homogenous fields. Whereas bee hive removal or protection is a suitable and common risk mitigation management tool to protect honey bees from pesticide exposure, there is no equivalent for other pollinating insects, especially for wild bees. In order to support ways to raise awareness about wild bees pollinate and forage on flowers of the field margin we developed a spatially explicit tool to assess the off-field risk to those insects from pesticide exposure. The tool incorporates the temporal occurrence and habitat preferences of more than 20 species common in agricultural landscapes in north-eastern Germany. The tool is meant to be used by farmers and advisors. We used geodata from the statewide biotope survey of Brandenburg to classify habitats according to the suitability for wild bees. With GIS we assessed the proportion of these feeding and nesting habitats with a range of 500m around cropland. Results

are aggregated on 1 sqkm hexagon level. We provide this habitat index for 22 529 tiles in total. The poster illustrates the spatial distribution of these habitats and gives example calculations for application patterns used in agricultural practice. The tool is implemented in a web based advisory and cooperation system for farmers, beekeepers and nature conservationists to exchange relevant information (e.g. location of apiaries, insecticide treatment) while respecting data privacy among the partners. The concept was developed within the project "geobee" which designs and implements a web based information platform for the protection and promotion of wild bees and honey bee. It provides free of charge technical services and information content in order to promote dialogue and information exchange between beekeeping and nature conservation and agriculture.

#### WEPC29

##### **Five point plan for a sustainable use of plant protection products**

T. Frische, Federal Environment Agency (UBA) / Section Plant Protection Products; S. Matezki, Plant Protection Products; C. Pickl, Federal Environment Agency Germany / Section IV Pesticides Fate and Behaviour Groundwater Risk Assessment; J. Wogram, German Federal Environment Agency UBA / Section Plant Protection Products

In 2009 the European Commission implemented the so-called "sustainable use directive" (Directive 2009/128/EC) in order to establish a framework for Community action to achieve the sustainable use of pesticides. Article 4 (1) of the directive re-quires: "*Member States shall adopt National Action Plans to set up their quantitative objectives, targets, measures and timetables to reduce risks and impacts of pesticide use on human health and the environment and to encourage the development and introduction of integrated pest management and of alternative approaches or techniques in order to reduce dependency on the use of pesticides.*" In Germany, the National Action Plan for sustainable use of plant protection products (PPP) was approved in spring 2013 by the government following an extensive multi-stakeholder debate. The German Federal Environment Agency (UBA) is in charge of the environmental risk assessment of PPP under Regulation (EC) No 1107/2009 as well as actively involved in the development and implementation of the German Action Plan. In this context, UBA developed five key principles / policy recommendations for a sustainable plant protection practice: Minimize PPP use Identify, quantify and communicate risks Optimize risk management Compensate inevitable ecological effects Internalize external costs The presentation will (i) explain the reasoning and motivation underlying these principles and (ii) discuss the actual and/or potential consideration of these principles in the National Action Plan and under the authorization procedure, respectively.

#### WEPC30

##### **Can the synergism of azole fungicides and pyrethroid insecticides observed in *D. magna* be quantified by measuring cytochrome P450 activity inhibition in vitro and in vivo ?**

M. Gottardi, N. Cedergreen, University of Copenhagen / Department of Plant and Environmental Sciences

Cocktail effects of chemical mixtures can to a large degree be predicted, as long as the chemicals do not interact with each other physically, chemically or biologically. However, if interactions take place, synergy can occur, which is defined as the mixture giving a larger biological effect than predicted by a reference model. A recent study has shown that for more than 95% of the pesticides synergies for which the mechanism is known, one of the chemicals either stimulates or inhibits the activity of enzymes involved in xenobiotic detoxification pathways. A group of these enzymes, Cytochrome P450, plays the major role in oxidation of drugs and other foreign compounds in a vast variety of species and its activation or inhibition seems to play a key role for the mode of action of a range of synergizing chemicals. The question is whether the degree of synergy can be predicted based on the knowledge of how synergistic chemicals affect the activity of these key enzymes. The P450 inhibition potential of several azole fungicides such as prochloraz, propiconazole, tebuconazole and epoxiconazole and the known P450 inhibitor piperonyl butoxide, are investigated with fluorescence spectroscopy toward cytochrome P450 (ECOD) activity of commercially available rat liver microsomes *in vitro* and of *D. magna* *in vivo*. The experimentally found inhibition potentials, expressed as the concentration giving a 50 % decrease in enzymatic activity relative to the control (IC<sub>50</sub>) are compared with the synergism observed in a previous study (expressed as fold increase in toxicity). The ability of the inhibition potentials to predict observed synergism is then evaluated and quantified.

## Atrazine. 318,474

## Behavior.

131,132,133,134,135,136,221,227,254,353,418,434,440,453,460,472,488,521,561,596,657,72,MO009,MO010,MO011,MO012,MO013,MO014,MO015,MO016,MO017,MO018,MO019,MO020,MO021,MO022,MO023,MO024,MO025,MO026,MO027,MO028,MO029,MO033,MO036,MO106,MO108,MO118,MO130,MO211,MO226,MO285,MO292,MO347,MO395,MO411,TH011,TH012,TH087,TH091,TH120,TH206,TH206,TU073,TU078,TU107,TU147,TU167,TU220,TU266,TU389,TU394,WE043,WE047,WE053,WE071,WE075,WE077,WE186,WE229,WE234,WE366,WE367,WE370

## Bioaccumulation.

105,106,132,143,150,151,165,181,182,203,269,270,271,272,285,312,326,334,341,343,344,345,347,353,405,406,417,42,427,44,45,46,471,479,493,540,541,542,544,553,611,615,645,647,656,657,658,660,670,672,676,677,88,93,94,MO005,MO010,MO012,MO049,MO077,MO079,MO112,MO116,MO128,MO130,MO185,MO188,MO192,MO205,MO208,MO212,MO216,MO217,MO254,MO276,MO279,MO300,MO323,MO327,MO327,MO422,MO427,MOPC17,TH008,TH018,TH033,TH033,TH052,TH057,TH059,TH060,TH067,TH072,TH072,TH076,TH078,TH080,TH125,TH125,TH176,TH180,TH201,TU015,TU019,TU032,TU035,TU042,TU045,TU051,TU053,TU064,TU066,TU081,TU082,TU083,TU086,TU089,TU091,TU098,TU100,TU124,TU159,TU160,TU172,TU173,TU176,TU177,TU181,TU183,TU203,TU259,TU261,TU262,TU267,TU346,TU347,TU357,TU418,TUPC14,TUPC25,WE008,WE015,WE036,WE079,WE097,WE107,WE111,WE114,WE151,WE152,WE153,WE156,WE159,WE181,WE191,WE201,WE211,WE212,WE214,WE215,WE216,WE217,WE220,WE222,WE223,WE224,WE225,WE226,WE227,WE229,WE230,WE231,WE274,WE308,WE359,WE375,WEPC04,WEPC06,WEPC15,WEPC26

## Bioavailability.

114,147,148,149,150,152,181,203,229,230,25,262,263,264,27,270,286,288,289,29,303,308,314,315,336,337,338,339,342,376,438,439,455,478

,556,61,62,63,64,645,66,666,698,699,89,90,91,96,MO122,MO126,MO183,MO184,MO185,MO186,MO187,MO191,MO192,MO195,MO196,MO197,MO199,MO202,MO203,MO204,MO211,MO215,MO217,MO298,MO301,MO311,MO323,MO340,MO345,MO348,MO389,MO389,MO402,MO404,MO405,MO406,MO407,MO408,MO409,MO410,MO411,MO412,MO413,MO415,MO417,MO418,MO419,MO422,MO423,MO441,MO446,MOPC05,MOPC10,TH014,TH052,TH174,TH186,TH202,TH207,TH208,TH208,TU018,TU022,TU024,TU025,TU032,TU039,TU045,TU047,TU047,TU065,TU070,TU075,TU077,TU096,TU122,TU123,TU124,TU125,TU126,TU131,TU168,TU170,TU242,TU262,TU350,TU351,TU418,TUPC17,TUPC26,WE090,WE102,WE137,WE156,WE212,WE213,WE263,WE299,WE360,WE362,WE380,WEPC03

## Bioconcentration.

135,393,456,471,472,540,543,545,665,690,MO018,MO061,MO078,MO080,MO101,MO278,MO419,MOPC03,TH031,TH046,TU157,TU179,WE149,WE150,WE211,WE218,WE222,WE223

## Biodegradation.

313,314,317,378,414,415,452,453,483,484,554,606,65,MO031,MO032,MO048,MO156,MO166,MO166,MO172,MO241,MO267,MO410,MO440,MO441,MO442,MO443,MOPC13,MOPC14,MOPC15,MOPC18,TH033,TH033,TH058,TH099,TU213,TU213,TU383,TU388,TU406,TU408,TUPC11,WE151,WE197,WE320,WE415

## Biomonitoring.

138,149,16,19,23,242,280,282,31,376,401,406,408,466,467,470,516,524,528,582,586,602,609,623,625,626,640,648,672,673,675,676,677,689,86,88,MO004,MO029,MO102,MO125,MO155,MO158,MO159,MO173,MO208,MO221,MO227,MO421,MO429,MO446,MOPC04,TH001,TH005,TH006,TH007,TH017,TH026,TH028,TH062,TH116,TH117,TH118,TH125,TH125,TH127,TH127,TH137,TH165,TH175,TH187,TU084,TU085,TU086,TU087,TU089,TU128,TU129,TU139,TU178,TU184,TU185,TU186,TU199,TU202,TU285,TU315,TU379,TU412,WE001,WE003,WE013,WE028,WE052,WE058,WE070,WE077,WE083,WE087,WE089,WE094,WE096,WE114,WE117,WE153,WE232,WE244,WE247,WE407,WE412,WEPC03,WEPC15

## Bioremediation.

16,313,314,317,379,MO154,MO268,MO410,MO411,MO445,TH203,TU267,TU376,TU382,TU388,TU398,TU405,TU407,TU408,TU411,TU414,TU419,TUPC20,WE247,WE273,WE323,WE323,WE353,WE353

## Biotransformation.

135,283,38,403,404,463,514,539,540,541,542,554,596,630,670,98,MO049,MO067,MO121,MO312,MOPC12,MOPC18,TH026,TH052,TH063,TU193,TU274,TUPC11,WE008,WE040,WE040,WE098,WE148,WE157,WE216,WE217,WE218,WE219,WE220,WE221,WE222,WE223,WE236,WE269

## Case study.

139,146,158,173,177,179,180,21,229,233,245,247,248,250,280,310,330,346,361,365,366,372,409,437,487,498,526,554,56,566,581,584,598,650,687,86,88,95,MO047,MO085,MO162,MO173,MO201,MO231,MO241,MO243,MO255,MO261,MO268,MO274,MO356,MO363,MO366,MO372,MO383,MO385,MO397,MO398,MO400,MOPC29,TH126,TH126,TH138,TH152,TH161,TH161,TH162,TH162,TH165,TH175,TH176,TH029,TU047,TU047,TU089,TU106,TU159,TU181,TU184,TU186,TU194,TU204,TU206,TU2

12,TU212,TU218,TU227,TU228,TU287,TU297,TU297,TU307,TU308,TU315,TU338,TU346,TU350,TU365,TU365,TU369,TU382,TU396,TU421,TUPC18,TUPC24,WE105,WE106,WE195,WE253,WE260,WE275,WE301,WE327,WE336,WE338,WE344,WE347,WE352,WE364,WE386,WE399

#### Chemical signalling.

142,653,TH047,TU068,WE029,WE199,WE290,WE290,WE291,WE291,WE319

#### Chronic toxicity.

138,140,202,206,360,363,389,397,411,442,458,47,473,517,525,589,MO003,MO023,MO027,MO038,MO050,MO056,MO061,MO067,MO068,MO070,MO071,MO090,MO090,MO091,MO091,MO111,MO114,MO139,MO162,MO299,MO304,MO306,MO307,MO317,MO423,MO434,MO435,MO449,MOPC06,MOPC15,TH010,TH013,TH021,TH030,TH030,TH081,TH094,TH095,TH097,TH138,TH166,TU003,TU007,TU023,TU025,TU026,TU027,TU099,TU127,TU182,TU224,TU246,TU276,TU279,TU280,TU314,TU318,TU325,TU421,WE003,WE010,WE017,WE026,WE030,WE061,WE062,WE064,WE107,WE120,WE123,WE138,WE155,WE241,WE245,WE278,WE283,WE298,WE315,WE391,WEPC25

#### Climate.

145,163,175,206,207,250,344,380,496,499,523,531,56,585,587,MO006,MO066,MO118,MO167,MO173,MO185,MO232,MO310,MO339,MO400,MOPC20,TH033,TH033,TH064,TU010,TU013,TU080,WE080,WE082,WE098,WE109,WE110,WE116,WE123,WE157,WE252,WE253,WE322,WE323,WE323,WE332,WE347,WEPC01,WEPC02,WEPC04

#### Cytotoxicity.

18,197,281,411,426,454,455,457,70,MO003,MO083,MO096,MO097,MO098,MO106,MO123,MO144,MO150,MO151,MO244,MO291,MO321,MO324,MO326,MO326,MO328,MO328,TH102,TH113,TU020,TU101,TU223,TU284,TU318,TUPC10,WE004,WE020,WE022,WE039,WE039,WE070,WE081,WE136,WE143,WE243,WE248,WE279,WE280,WE294,WE313,WE313

#### Decision analysis.

113,123,128,129,16,172,178,246,431,435,448,468,502,537,671,MO168,MO363,MO398,MO428,MOPC29,TH036,TH151,TH155,TU303,TU306,TU368,TUPC31,WE181,WE313,WE313,WE332,WE335,WE343,WE355,WE355,WE424

#### Degradation.

212,380,381,39,421,510,511,513,537,598,650,664,98,MO030,MO154,MO235,MO236,MO237,MO336,MO337,MO338,MO339,MO347,MO352,MO444,MO447,MOPC14,MOPC16,MOPC17,MOPC22,TH037,TH039,TH040,TH041,TH054,TH058,TH069,TH069,TH192,TU071,TU136,TU153,TU164,TU225,TU345,TU353,TU380,TU385,TU393,TU394,TU399,WE134,WE165,WE166,WE183,WE184,WE185,WE241,WE265,WE268,WE395,WE410

#### Depuration.

487,MO130,MO223,TH029,TH059,TU074,TU379,TU386,TU388,WE233,WE246,WE271,WE308

#### Desorption.

217,271,33,61,697,MO234,MO417,TU073,TU075,TU153,TU155,TU255

#### Development.

11,199,246,269,292,355,357,391,412,417,460,480,521,6,601,602,614,629,641,694,8,MO026,MO062,MO092,MO092,MO095,MO135,MO135,

MO178,MO221,MO226,MO227,MO247,MO375,MO397,MO414,MO448,MO450,MOPC07,MOPC11,MOPC12,TH168,TH169,TH203,TU007,TU012,TU013,TU052,TU152,TU172,TU236,TU276,TU281,TU296,TU296,TU328,TU343,TU374,TU413,WE007,WE023,WE026,WE034,WE044,WE054,WE066,WE109,WE119,WE130,WE168,WE182,WE213,WE252,WE291,WE291,WE293,WE293,WE317,WE331,WE354,WE354,WEPC15

#### Dioxins.

162,331,62,MO024,MO253,MO268,MO273,TH078,TH197,TU125,TU140,TU202,TU273,TU274,TU354,WE185

#### Ecological risk assessment.

1,113,116,13,137,141,156,181,186,20,200,206,21,223,261,264,332,334,358,364,388,390,398,40,408,427,446,447,468,470,504,506,508,518,523,524,528,529,53,531,533,541,542,549,557,558,568,580,581,586,587,616,619,621,630,632,647,651,662,679,680,681,682,689,69,78,85,86,87,MO047,MO055,MO073,MO084,MO090,MO090,MO096,MO100,MO115,MO129,MO163,MO163,MO166,MO166,MO212,MO258,MO345,MO347,MO348,MO357,MO385,MO403,MO413,MO419,MO420,MO425,MO426,MO429,MO432,MO434,MO437,MOPC02,MOPC04,MOPC19,MOPC21,MOPC25,MOPC30,TH001,TH004,TH008,TH026,TH027,TH036,TH039,TH051,TH055,TH057,TH058,TH061,TH062,TH076,TH088,TH093,TH095,TH109,TH128,TH130,TH133,TH134,TH135,TH137,TH138,TH140,TH141,TH146,TH147,TH147,TH178,TH187,TH195,TU001,TU002,TU005,TU011,TU017,TU030,TU035,TU041,TU044,TU049,TU049,TU063,TU080,TU099,TU102,TU103,TU107,TU108,TU112,TU113,TU116,TU129,TU168,TU180,TU201,TU218,TU226,TU293,TU293,TU294,TU294,TU309,TU311,TU312,TU315,TU320,TU323,TU324,TU326,TU329,TU333,TU338,TU339,TU341,TU342,TU343,TU355,TU357,TU358,TU361,TU365,TU365,TU367,TU367,TU368,TU371,TU412,TUPC04,TUPC05,TUPC06,TUPC17,TUPC31,TUPC32,TUPC33,TUPC35,TUPC36,WE004,WE006,WE012,WE018,WE024,WE030,WE046,WE052,WE058,WE068,WE071,WE107,WE128,WE130,WE136,WE160,WE185,WE217,WE244,WE247,WE249,WE330,WE361,WE367,WE368,WE369,WE370,WE372,WE376,WE377,WE378,WE381,WE400,WE403,WE426,WEPC01,WEPC06,WEPC14,WEPC16,WEPC25,WEPC26,WEPC27

#### Ecotoxicology.

The Society of Environmental Toxicology and Chemistry (SETAC) is a not-for-profit, global professional organisation comprised of some 5500 individual members and institutions dedicated to the study, analysis and solution of environmental problems, the management and regulation of natural resources, research and development, and environmental education. SETAC Europe is one of the five Geographic Units of the global Society, established to promote and undertake activities of SETAC in Europe, and to support activities of SETAC in the Middle East and Africa. The Society is dedicated to the use of multidisciplinary approaches to examine the impacts of stressors, chemicals and technology on the environment. We also provide an open forum for scientists and institutions engaged in the study of environmental problems, management and regulation of natural resources, education, research and development, and manufacturing. SETAC Europe is incorporated in Belgium as a not-for-profit organisation. The Society is governed according to its articles of association and by-laws. SETAC Europe maintains its administrative office in Brussels, Belgium.
